Abstract

A model that gives family gauge bosons with an inverted mass hierarchy is proposed, stimulated by Sumino’s cancellation mechanism for the QED radiative correction to the charged lepton masses. The Sumino mechanism cannot straightforwardly be applied to SUSY models because of the non-renormalization theorem. In this talk, an alternative model which is applicable to a SUSY model is proposed. It is essential that family gauge boson masses $m(A_i)$ in this model is given by an inverted mass hierarchy $m(A_i) \propto \frac{1}{\sqrt{m_{ei}}}$, in contrast to $m(A_i) \propto \sqrt{m_{ei}}$ in the original Sumino model. Phenomenological meaning of the model is also investigated. In particular, we notice a deviation from the $e$-$\mu$ universality in the tau decays.

1 Motive to consider an inverted mass hierarchy

In this section, it is discussed why we consider a family gauge boson model with an inverted mass hierarchy. However, since our model has been stimulated by a Sumino mechanism, prior to giving our motive, we would like to give a brief review of the Sumino mechanism.

1.1 Why did Sumino need a family gauge symmetry?

In 2009, Sumino \textsuperscript{11} has seriously taken why the mass formula \textsuperscript{2}

$$K \equiv \frac{m_e + m_\mu + m_\tau}{(\sqrt{m_e} + \sqrt{m_\mu} + \sqrt{m_\tau})^2} = \frac{2}{3},$$

(1)

is so remarkably satisfied with the pole masses: $K^{\text{pole}} = (2/3) \times (0.999989 \pm 0.000014)$. However, in a mass matrix model, usually, “masses” do not mean “pole masses”, but “running masses”. The formula (1) is only valid with the order of $10^{-3}$ for the running masses, e.g. $K(\mu) = (2/3) \times (1.00189 \pm 0.00002)$ at $\mu = m_Z$. The deviation of $K(\mu)$ from $K^{\text{pole}}$ is caused by a logarithmic term $m_{ei} \log(\mu/m_{ei})$ in the QED radiative correction term \textsuperscript{3}

$$m_{ei}(\mu) = m_{ei}^{\text{pole}} \left[ 1 - \frac{\alpha_{em}(\mu)}{\pi} \left( 1 + \frac{3}{4} \log \frac{\mu^2}{m_{ei}^2(\mu)} \right) \right].$$

(2)

\textsuperscript{11} Talk presented by Y. Koide at International Workshop on Grand Unified Theories (GUT2012), March 15-17, 2012 at YITP, Kyoto, Japan. To appear in the proceedings which will be published by AIP.
Meanwhile, under the transformation $m_i \to m_i (1 + \varepsilon_0 + \varepsilon_i)$, where $\varepsilon_0$ and $\varepsilon_i$ are family-number independent and dependent factors, respectively, the ratio $K$ is invariant if $\varepsilon_i = 0$. That is, $\varepsilon_i$ term corresponds to the log $m_{ei}$ term in (2). If we can remove the log $m_{ei}$ term, we can build a model with $K_{pole} = K(\Lambda)$. Therefore, Sumino [1] has proposed an idea that the log $m_{ei}$ term is canceled by a contribution from family gauge bosons as shown in Fig. 1.

$$\psi_L \rightarrow \psi_R$$

$$m_i(\mu)$$

Figure 1: The Sumino mechanism

In order to work the Sumino mechanism correctly the following conditions are essential: (i) the left- and right-handed charged leptons $e_{Li}$ and $e_{Ri}$ are assigned to 3 and $3^*$ of a U(3) family symmetry, respectively; (ii) masses of the gauge bosons $A_j^i$ are given by

$$M_{ij} \equiv m(A_j^i) \propto \sqrt{m_{ei} + m_{ej}} \quad (3)$$

Thus, the contribution $-g_\mu^2 \log M_{ii}^2$ term from the family gauge bosons can cancel the $e^2 \log m_{ei}^2$ term.

Now, we want to apply this mechanism to a SUSY model. However, note that the contribution given in Fig. 1 (b) is zero in a SUSY model because it is a vertex correction type. Therefore, the Sumino mechanism cannot apply to a SUSY model.

1.2 Our motive

Here, we propose a Sumino-like mechanism which can work in a SUSY model. We notice the diagram (a) in Fig. 2.

$$\varepsilon_i = \rho \left( \log \frac{m_{ei}^2}{\mu^2} + \zeta \sum_j \log \frac{M_{ij}^2}{\mu^2} \right), \quad \rho = \frac{3 \alpha_{em}}{4 \pi}, \quad \zeta = \frac{2}{3} \alpha_F, \quad (4)$$

Figure 2: Contributions from family gauge bosons
In order that the cancellation works correctly, since $\zeta > 0$, we must consider

$$M_{ij}^2 \propto \frac{1}{m_{ei}} + \frac{1}{m_{ej}}, \quad (5)$$

differently from the Sumino’s gauge boson mass relation (3).

Note that since the gauge bosons $A_j^i$ with $j \neq i$ can contribute to the $\varepsilon_i$ term, differently from the Sumino model, the QED log $m_{ei}$ term cannot be canceled by the gauge boson terms exactly. However, practically, the cancellation $R - 1$ ($R \equiv K(m_{ei})/K(m_{ei}^0)$ can be smaller than $10^{-5}$ at $\zeta = 7/4$.

2 Outline of the model

By introducing two types of scalars $\Phi^i_\alpha$ (and $\bar{\Phi}^i_\alpha$) and $\Psi^i_\alpha$ (and $\bar{\Psi}^i_\alpha$) which are $(3, 3^*)$ ($(3^*, 3)$) of family symmetries $SU(3) \times SU(3)'$, we build our model as follows:

(i) The charged lepton mass matrix $M_e$ is given by

$$M_e \propto \langle \bar{\Phi} \rangle \langle \Phi \rangle. \quad (6)$$

(ii) Family gauge boson masses $M_{ij}$ are dominantly given by the VEV $\langle \Psi \rangle$. Therefore, we must show

$$\langle \Psi \rangle \gg \langle \Phi \rangle. \quad (7)$$

(iii) Gauge bosons take an inverted mass hierarchy: We must show

$$\langle \Psi \rangle \langle \Phi \rangle \propto 1. \quad (8)$$

The conditions (i), (ii) and (iii) are derived from the following superpotentials [4]

$$W_Y = y_\ell \bar{\ell}_i \Phi^i_\alpha \bar{L}^\alpha + y_H d L \alpha H_d E^{e\alpha} + y_e \bar{E}^c \Phi^c_\alpha e^c_j + M_E E^{e\alpha} \bar{E}^c + M_L L \alpha \bar{L}^\alpha,$$

$$W_{\Phi} = \lambda_1 \Phi^i_\alpha \bar{\Phi}^i_\alpha \theta_\Phi - \lambda_2 S^2 \theta_\Phi, \quad W_{br} = \mu S \theta_S - \varepsilon \mu S \theta_S,$$

$$W_{\Phi \Psi} = \left( \lambda_A \Phi^i_\alpha \bar{\Psi}^i_\beta + \bar{\lambda}_A \bar{\Phi}^i_\alpha \bar{\Psi}^i_\beta \right) (\Theta_A)^i_\alpha \left( \lambda_A \Phi^i_\alpha \bar{\Psi}^i_\beta + \bar{\lambda}_A \bar{\Phi}^i_\alpha \bar{\Psi}^i_\beta \right) (\Theta_A)^i_\alpha$$

respectively. As a result, we obtain

$$\langle \Phi \rangle = \langle \bar{\Phi} \rangle = v_\Phi Z, \quad \langle \Psi \rangle = \langle \bar{\Psi} \rangle = v\Psi Z^{-1}, \quad (12)$$

where

$$Z = \text{diag}(z_1, z_2, z_3), \quad (13)$$
and the parameter values of $z_i$ are given by

$$z_i = \frac{\sqrt{m_{e_i}}}{\sqrt{m_{e1}} + m_{e2} + m_{e3}},$$  \hspace{1cm} (14)$$

where $(m_{e1}, m_{e2}, m_{e3}) = (m_e, m_\mu, m_\tau)$. The explicit values of $z_i$ are given by $(z_1, z_2, z_3) = (0.016473, 0.23688, 0.97140)$. Thus, we can approximately estimate the family gauge boson masses $m(A^i_j)$ as follows

$$M^2_{ij} \equiv m^2(A^i_j) \simeq g_F^2 v_\Psi^2 \left( \frac{1}{z_i^2} + \frac{1}{z_j^2} \right) \propto \left( \frac{1}{m_{e_i}} + \frac{1}{m_{e_j}} \right),$$  \hspace{1cm} (15)$$

if the mixing between the U(3) and U(3)$'$ gauge bosons can be neglected. This happens when the latter gauge bosons are sufficiently heavy.

However, for reasons of my talk time, I would like to skip the details of the model. For more details, see our recent paper [4].

3 How different from the Sumino model?

Let us give only a summary table for differences between Sumino model and ours in Table 1.

Table 1: Comparison between the Sumino model and the present model.

4 How to observe the gauge boson effects

Note that the family number is defined on the diagonal basis of the charged lepton mass matrix $M_e$. Hadronic modes are in general dependent on the quark mixing matrices $U_u$ and $U_d$. We know the observed values of $V_{CKM} = U^\dagger_u U_d$, but we do not know values of $U_u$ and $U_d$ individually.

In the present model, we do not give an explicit model for quark mixings on the diagonal basis of $M_e$. A constraint from $K^0-\bar{K}^0$ mixing is highly dependent on a model of $U_d$. We will not discuss it in this talk.
4.1 Deviation from the $e$-$\mu$ universality in the tau decays

The pure-leptonic decays are independent of a model of the quark mixing. Therefore, first, we discuss the deviation from the $e$-$\mu$ universality in the tau decays.

We have family current-current interactions

$$ G_{ij}/\sqrt{2} = g_i^2/2M_{ij}^2 \simeq z_i^2/2v^2_\Psi, $$

where $G_{ij}/\sqrt{2} = g_i^2/2M_{ij}^2 \simeq z_i^2/2v^2_\Psi$, in addition to the conventional weak interactions

$$ GF/\sqrt{2} = g_2^2W/8M^2_W = 1/2v^2_W, $$

where $GF/\sqrt{2} = g_2^2W/8M^2_W = 1/2v^2_W$.

![Figure 3: Deviation from $e$-$\mu$ universality in tau decays](image)

We obtain a deviation from the $e$-$\mu$ universality as follows:

$$ R_\tau \equiv \frac{1 + \epsilon_\mu}{1 + \epsilon_e} = \left[ \frac{B(\tau^- \to \mu^-\bar{\nu}_\mu\nu_\tau)}{B(\tau^- \to e^-\bar{\nu}_e\nu_\tau)} \right]^{1/2}, $$

where $f(m_e/m_\tau)/f(m_\mu/m_\tau) = 1.028215$ and

$$ \epsilon_\mu \simeq \frac{1}{4}z_2^2r^2 = 1.4 \times 10^{-2}r^2, \quad \epsilon_e \simeq \frac{1}{4}z_1^2r^2 = 6.8 \times 10^{-5}r^2, $$

with $r = v_W/v_\Psi$ ($v_W = 246$ GeV). Present experimental values [5]

$$ B(\tau^- \to \mu^-\bar{\nu}_\mu\nu_\tau) = (17.39 \pm 0.04)\%, \quad B(\tau^- \to e^-\bar{\nu}_e\nu_\tau) = (17.82 \pm 0.04)\% $$

give

$$ R^{\exp}_\tau = 1.0017 \pm 0.0016, \quad \text{i.e. } \epsilon_\mu \simeq 0.0017 \pm 0.0016. $$

This result seems to be in favor of the inverted gauge boson mass hierarchy although it is just at 1 $\sigma$ level. (If the gauge boson masses take a normal hierarchy, $R_\tau$ will show $R_\tau < 1$.) At present, we should not take the value [21] rigidly. If we dare to adopt the center value in [21], we obtain $r \sim 0.35$ ($v_\Psi \sim 0.7$ TeV). This value of $v_\Psi$ seems to be somewhat small. We speculate $r \sim 10^{-1}$, i.e. $v_\Psi \sim$ a few TeV. The value will be confirmed by a tau factory in the near future.
4.2 Family number conserved semileptonic decays of ps-mesons

Branching ratios of family number conserved semileptonic decays are not sensitive to explicit values of the quark mixings $U_u$ and $U_d$. We predict those in the limit of $U_u = 1$ and $U_d = 1$:

\[
\begin{align*}
B(K^+ \to \pi^+ \mu^+ e^-) & \sim 5 \times 10^{-12} \quad (< 1.3 \times 10^{-11}), \\
B(K_L \to \pi^0 \mu^+ e^+) & \sim 1 \times 10^{-11} \quad (< 7.6 \times 10^{-11}), \\
B(D^+ \to \pi^+ \mu^- e^+) & \sim 6 \times 10^{-13} \quad (< 3.4 \times 10^{-5}), \\
B(D^0 \to \pi^0 \mu^- e^+) & \sim 1 \times 10^{-13} \quad (< 8.6 \times 10^{-5}), \\
B(B^+ \to K^+ \mu^- \tau^+) & \sim 2 \times 10^{-6} \quad (< 7.7 \times 10^{-5}), \\
B(B^0 \to K^0 \mu^- \tau^+) & \sim 2 \times 10^{-6} \quad \text{(no data)}.
\end{align*}
\]

Here, the values in parentheses are present experimental upper limits \[5\]. For reference, we illustrate the predicted branching ratios in Fig. 4. As seen in Fig. 4, if $v_{\Psi}$ is a few TeV, observations of the lepton-flavor violating $K$- and $B$-decays with $\Delta N_F = 0$ will be within our reach.

4.3 Direct searches at LHC and ILC

Since we speculate that $v_{\Psi}$ is of the order of a few TeV, we may expect that the lightest family gauge boson $A_3$ is also of the order of a few TeV. The experimental search is practically the same as that \[6\] for $Z'$ boson, but we will see only peak in $\tau^+ \tau^-$ channel (no peaks in $e^+ e^-$ and $\mu^+ \mu^-$ channels). Possible productions of $A_3$ at the LHC and ILC are illustrated in Figs. 5 and 6 respectively.
5 Summary

The Sumino mechanism does not work for a SUSY model. In order to work a Sumino-like mechanism for a SUSY model, we must consider a family gauge boson model with an inverted mass hierarchy. Whether the gauge boson masses are inverted or normal is confirmed by observing the deviation from the e-μ universality in the pure leptonic tau decays, i.e. $R_\tau > 1$ or $R_\tau < 1$. The present observed values show $R_\tau^{exp} = 1.0017 \pm 0.0016$ which is in favor of the inverted mass hierarchy. Since we speculate that the lightest gauge boson mass is a few TeV, we expect the deviation $\Delta R_\tau \equiv R_\tau - 1 \sim 10^{-4}$. A tau factory in the near future will confirm this deviation. We also expect a direct observation of $\tau^+\tau^-$ in the LHC and the ILC.
