ABSTRACT
In this paper we use one of the Post-Keplerian parameters to obtain constraints on $f(R)$-theories of gravity. Using Minkowskian limit, we compute the prediction of $f(R)$-theories on the first time derivative of the orbital period of a sample of binary stars, and we use our theoretical results to perform a comparison with the observed one. Selecting a sample of relativistic binary systems we estimate the parameters of an analytic $f(R)$-gravity. We find that the theory is not ruled out if we consider only the double neutron star systems, and in this case we can cover the existing gap between the General Relativity prediction and the observed data.

Key words: gravitation – binary pulsar systems.

1 INTRODUCTION
The gravitational waves (GWs) are one of the most promising tools to study astrophysical systems like Neutron Stars (NS), coalescing binary systems, Black Holes (BHs), and White Dwarfs (WDs).

The observational indirect evidences of gravitational radiation were measured on the system B1913+16, known as the Hulse-Taylor binary pulsar, and confirmed in others relativistic binary systems. The prediction of General Relativity (GR) on the first time derivative of the orbital period in binary pulsar systems was studied by Hulse and Taylor (1975) and Weisberg et al. (2010), for which the discrepancy on observed data with respect to the prediction is $\sim 1\%$. However, the observational results should be explained using a different formulation of gravity (Freire et al. 2012). As shown in De Laurentis and Capozziello (2011), these systems could represent a good test for Extended Theories of Gravity (ETG). Considering a class of analytic $f(R)$-theories, it is possible evaluate the gravitational radiated power in weak field limit. In this approximation we find that the energy radiated depends on the third derivative of the quadrupole, as predicted by GR, and the fourth derivative representing the corrective contribution to the theory. This result can be used to set constraints on the theory, comparing the prediction on the first time derivatives of the orbital period with respect to the observed one. The outline of the paper is the following: in sec. 2 we briefly introduce the weak field limit approximation of $f(R)$-theories of gravity. In sec. 3 we apply the theoretical results previously obtained to binary systems computing the energy lost through GWs emission. In sec. 4 we compute the first time derivative of the orbital period in $f(R)$-theories of gravity, and we compare the theoretical prediction with the observed data. Finally, in sec. 5 we give our conclusions and remarks.

2 F(R)-GRAVITY BACKGROUND
The $f(R)$-theories are based on corrections and enlargements of the GR theory adding higher-order curvature invariants and minimally or non-minimally coupled scalar fields into dynamics which come out from the effective action of quantum gravity (Capozziello and De Laurentis 2011).

Starting from the following field equations in $f(R)$-gravity (looking for major details at Capozziello and De Laurentis 2011).

f( R) = \sum_{n>0} \frac{f^{(n)}(R_0)}{n!} (R - R_0)^n \approx f_0 + f_0' R + \frac{f_0''}{2} R^2 + \ldots \quad (3)

At the first order, in term of the perturbations, the field equations become

\[ f_0' \left[ R^{(1)}_{\mu\nu} - \frac{R^{(1)}}{2} \eta_{\mu\nu} \right] - f_0'' \left[ R^{(1)}_{\mu\nu} - \eta_{\mu\nu} \Box R^{(1)} \right] = \frac{\mathcal{X}}{2} T^{(0)}_{\mu\nu}, \quad (4) \]

where \( f_0' = \frac{df}{dR} \big|_{R=0} \) and \( f_0'' = \frac{d^2f}{dR^2} \big|_{R=0} \) and \( \Box = \partial^\alpha \partial^\alpha \) is the d'Alembert operator. Here, the Ricci tensor and scalar read

\[
\begin{align*}
R^{(1)}_{\mu\nu} &= h^{(1)}_{\mu\nu} + \frac{1}{2} \partial h_{\mu\nu} - \frac{1}{2} h_{\mu\nu}, \\
R^{(1)} &= h_{\sigma\tau} \partial^{\sigma\tau} - \Box h
\end{align*}
\]

Now, assuming that the source is localized in a finite region, as a consequence outside this region \( T^{(0)}_{\mu\nu} = 0 \) and

\[ R^{(1)}_{\mu\nu} = \Box h_{\mu\nu} = 0. \quad (6) \]

From here it is possible calculate the energy momentum tensor of gravitational field in \( f(R) \)-gravity, adopting the definition given in Landau and Lifshitz (1962) and De Laurentis and Capozziello (2011), so that it satisfies a conservation law as required by the Bianchi identities:

\[
\begin{align*}
t^\lambda_{\alpha} &= \frac{1}{\sqrt{-g}} \left[ \frac{\partial}{\partial g_{\rho\sigma,\alpha}} - \partial^\xi \frac{\partial}{\partial g_{\rho\sigma,\xi}} \right] g_{\rho\sigma,\alpha} + \\
&\quad + \frac{\partial}{\partial g_{\rho\sigma,\xi}} g_{\rho\sigma,\alpha} - \delta^\lambda_{\alpha} \frac{\partial}{\partial g_{\rho\sigma,\xi}} \right] .
\end{align*}
\]  

\[
(7)
\]

Starting from above equation, De Laurentis and Capozziello (2011) have shown that the energy momentum tensor consists of a sum of a GR contribution plus a term coming from \( f(R) \)-gravity

\[
t^\lambda_{\alpha} = f_0^T t^\lambda_{\alpha|GR} + f_0'' t^\lambda_{\alpha|f(R)},
\]

\[
(8)
\]

that in term of the perturbation \( h \) is

\[
T_{\mu\nu} = -\frac{2}{\sqrt{-g}} \delta(\sqrt{-g} \mathcal{L}_h) \quad (9)
\]

is the energy momentum tensor of matter (\( T \) is the trace), \( \mathcal{X} = \frac{16\pi G}{c^4} \) is the coupling,

\[ f'(R) \right|_{\Box = \partial^\alpha \partial^\alpha} \text{ and } \Box = \partial^\alpha \partial^\alpha \text{ denote the Schrödinger potential and the Peierls bracket of } \mathcal{L}_h \text{, respectively.}
\]

1. For convenience we use \( f \) instead of \( f(R) \). All considerations are developed here in metric formalism. From now on we assume physical units \( G = c = 1 \).

2. For convenience we use \( f \) instead of \( f(R) \). All considerations are developed here in metric formalism. From now on we assume physical units \( G = c = 1 \).
the time derivatives using the following relation given in 

\[ \langle t^n_i \rangle = \left\langle f'_0 k_0 \frac{4}{r^2} \left[ (\dot{x}_i \dot{r}^2 \dot{Q}^{ij}) - 2 (\dot{x}_i \ddot{Q}^{ij}) \right] + \frac{1}{r^2} \left[ (\dot{x}_i \dddot{Q}^{ij}) - f'_0 \delta_i^j (k_p k_r)^2 \right] \right\rangle. \] 

(16)

Using the result in eq. (14) and integrating over all directions they computed the total average flux of energy due to the tensor wave,

\[ \frac{dE}{dt} = \frac{G}{60} \left( f'_0 \left( \frac{Q^{ij} Q_{ij}}{Q} \right) - f''_0 \left( \frac{\dddot{Q}^{ij} Q_{ij}}{Q} \right) \right). \] 

(17)

Precisely, for \( f''_0 \to 0 \) and \( f'_0 \to \frac{4}{r^2} \), eq. (17) becomes

\[ \frac{dE}{dt} = \frac{G}{60} \left\langle \frac{\dot{Q}^{ij} Q_{ij}}{Q} \right\rangle, \] 

(18)

which is the well-known result of GR (Landau and Lifshitz 1962, Weinberg 1972). An important remark is related to the absence of monopole and dipole terms in our considerations. In our case, all the calculations are performed in the Jordan frame so \( f(R) \)-gravity results as a mere extension of GR being \( f(R) = R \), so any dipole terms is null (as shown in Will 1993 in table 10.2). In order to put in evidence such contributions, we have to pass in the Einstein frame where the additional degrees of freedom of gravitational field can be recast in terms of scalar fields. In this case, monopole and dipole terms explicitly come out (Will 1993, Naef and Jetzer 2011, Damour and Esposito-Farese 1996).

The two approaches are conformally equivalent but in the Einstein frame monopole and dipole terms can come out (see, e.g., Capozziello and De Laurentis 2011).

### 4 APPLICATION TO PULSAR BINARY SYSTEMS

Now, our goal is to use a sample of binary pulsar systems to fix bounds on \( f(R) \) parameters. To do this, we assume that the motion is Keplerian and the orbit is in the \((x, y)\)-plane.

We define \( m_p \) as the pulsar mass, \( m_c \) as the companion mass, and \( \mu = \frac{m_c m_p}{m_c + m_p} \) as the reduced mass. In \((x, y)\)-plane the quadrupole matrix is

\[ Q_{ij} = \mu r^2 \left( \begin{array}{cc} \cos^2 \psi & \sin \psi \cos \psi \\ \sin \psi \cos \psi & \sin^2 \psi \end{array} \right), \] 

(19)

where \( i, j \) are the indexes in the orbital plane, \( r \) is the equation of the elliptic Keplerian orbit and \( \psi \) is eccentric anomaly, and both of them are time dependent.

To compute the radiated power we need the third and fourth derivatives of quadrupole, so we must compute the time derivatives using the following relation given in [Maggiore (2007)]

\[ \ddot{\psi} = \left( \frac{Gm_c}{a^3} \right)^{\frac{1}{2}} (1 - e^2)^{-\frac{3}{2}} (1 + \epsilon \cos \psi)^2, \] 

(20)

where \( a \) is the semi-major axis, and \( \epsilon \) is the orbital eccentricity. We obtain the following relations for the time derivatives of the quadrupole

\[ \ddot{Q}_{11} = \mathcal{H}_1 \sin 2\psi (\epsilon \cos \psi + 1)^2 (3 \epsilon \cos \psi + 4), \] 

\[ \ddot{Q}_{22} = -\mathcal{H}_1 (8 \cos \psi + \epsilon (3 \cos 2\psi + 5)) \times \sin \psi (\epsilon \cos \psi + 1)^2, \] 

\[ \dddot{Q}_{12} = -\mathcal{H}_1 (\epsilon \cos \psi + 1)^2 \times (5 \epsilon \cos \psi + 3 \epsilon \cos 3\psi + 8 \cos 2\psi), \] 

(21)

(22)

(23)

\[ \dddot{Q}_{11} = \mathcal{H}_2 \left[ 15 \epsilon \cos 4\psi + 50 \epsilon \cos 3\psi \right. \] 

\[ \left. + \left( 12 \epsilon^2 + 32 \right) \cos 2\psi + 6 \epsilon \cos \psi - 3 \epsilon^2 \right], \] 

(24)

\[ \dddot{Q}_{22} = -\mathcal{H}_2 \left[ 15 \epsilon^2 \cos 4\psi + 50 \epsilon \cos 3\psi + \right. \] 

\[ \left. + \left( 24 \epsilon^2 + 32 \right) \cos 2\psi + 14 \epsilon \cos \psi - 7 \epsilon^2 \right], \] 

(25)

\[ \dddot{Q}_{12} = 2 \mathcal{H}_2 \sin \psi \left[ 15 \epsilon \cos 3\psi + 50 \epsilon \cos 2\psi \right. \] 

\[ \left. + \left( 33 \epsilon^2 + 32 \right) \cos \psi + 30 \epsilon \right], \] 

(26)

where

\[ \mathcal{H}_1 = \frac{(2 \pi)^{5/3} G^{2/3} m_c m_p}{T^{5/3} (1 - e^2)^{5/2} \sqrt{m_c + m_p}}, \]

\[ \mathcal{H}_2 = \frac{2^{2/3} \pi^{8/3} G^{2/3} m_c m_p (\epsilon \cos \psi + 1)^3}{T^{8/3} (1 - e^2)^4 \sqrt{m_c + m_p}}. \]

Now, from eq. (17), we can perform the time average of the radiated power writing

\[ \left\langle \frac{dE}{dt} \right\rangle = \frac{1}{T} \int_0^T dt \frac{dE(\psi)}{dt} = \frac{1}{T} \int_0^{2\pi} \frac{d\psi}{\psi} dE(\psi), \] 

(27)

and finally we get the first time derivative of the orbital period

\[ \dot{T}_b = -\frac{3}{20} \left( \frac{T}{2\pi} \right)^{\frac{1}{2}} \mu \frac{G^2 (m_c + m_p)^2}{c^5 (1 - e^2)^{3}} \times \left[ f'_0 \left( 37 \epsilon^4 + 292 \epsilon^2 + 96 \right) - \frac{f'_0 \pi^2 T^{-1}}{2(1 + \epsilon^2)^3} \times \left( 891 \epsilon^8 + 2801 \epsilon^6 + 82736 \epsilon^4 + 43520 \epsilon^2 + 3072 \right) \right]. \] 

(28)

In the next section we will go on to constraint the \( f(R) \)-theories estimating \( f'_0 \) from comparison between the theoretical predictions of \( \dot{T}_b \) and the observed one.
4.1 Comparing theory prediction with data

It is well known that in the relativistic binary pulsar systems there is a loss of energy due to GWs emission. This energy loss, provided by GR, has been confirmed by the timing data analysis on the well known binary pulsar B1913+16 (Hulse and Taylor 1974; Weisberg et al. 2010). We also must note that the systems like B1913+16 are optimal tools to constrain theories of gravitation (Damour and Esposito-Farese 1998) using the Post-Keplerian parameters. For sake of convenience we choose the observed orbital period derivative $\dot{T}_b$, because it is one of the best observed Post-Keplerian parameters. Moreover we know, according to GR theory, that it is related to the foreseen orbital decay due to quadrupole gravitational radiation emitted by the binary systems.

As shown in sec. 4 it is possible rewrite the first derivative of the orbital period in $f(R)$-theories of gravity. In principle, if we know exactly which Lagrangian we have to use to describe those type of systems, then we can predict the energy loss through GWs radiation. Here, we want to make the inverse process, to get an estimation of the second derivative $f''_0$ imposing the strong hypothesis that the difference between the observed binary period variation ($\dot{T}_{b,\text{obs}} \pm \delta$) and the one obtained by the relativistic theory of gravitation, $\Delta \dot{T}_b = \dot{T}_{b,\text{obs}} - \dot{T}_{GR}$, is fully justified imposing that:

$$\dot{T}_{b,\text{obs}} - \dot{T}_{GR} - f''_0 \dot{T}_{b,R}(r) = 0,$$

and propagating the experimental error, $\pm \delta$, on the first derivative of the observed orbital period $\dot{T}_{b,\text{obs}}$, into an uncertainty on second derivative of gravitational theory, $f''_0$. What we want to emphasize is that, where GR is not able to fully explain the loss of energy by emission of GWs radiation then, the additive contribution of ETGs can provide a way to fill the gap between theory and observations. We have also substituted the external contributions to the orbital decay as galactic or Shklovskii acceleration when those values are available in literature. Solving the eqs. (29) and (30) for $f''_0$, we get an estimation of $f''_0$ and its upper and lower limits corresponding respectively to $\mp \delta$. In this way $\Delta \dot{T}_b$ is fully explained through the orbital period correction due to the ETGs $\dot{T}_{b,R}(r)$. So we get:

$$f''_0 = \frac{\Delta \dot{T}_b}{\dot{T}_{b,R}(r)},$$

and the one obtained by the relativistic theory of gravitation, $\dot{T}_{b,\text{obs}}$, for the predicted second derivative $f''_0$ computed orbital period variation from general relativistic theory $\dot{T}_{GR}$, the orbital eccentricity $e$, the masses of the components $m_p$ and $m_e$, are known with a fairly good precision. For each system we have chosen, all previous parameters and their references are reported in Tab. 1 where we show: the J-Name of the binary pulsar system, the observed orbital binary period $T_{b,\text{obs}}$ in days, the orbital projected semi-major axis $a$ ($\text{asin}(i)$) in light second, the orbital eccentricity $e$, the observed time variation of the orbital period $T_{b,\text{obs}}$, the predicted one $T_{GR}$ (according to the GR theory), the experimental error $\pm \delta$ on $T_{b,\text{obs}}$, and the masses $m_p$ and $m_e$ of the binary system components in solar mass unit.

Furthermore, in Tab. 2 we reported: the J-Name of the systems, the difference $\Delta T_{GR}$ between $T_{b,\text{obs}}$ and $T_{GR}$ (equal to the correction $-f''_0 \dot{T}_{b,R}(r)$), the correction $\dot{T}_{b,R}(r)$, the corresponding $f''_0$ solution of (29) shown in (31), the interval centered on $f''_0$ and finally, the interval centered on $f'_0$ and computed from the difference $f''_{0,\pm} - f'_0$, where $f''_{0,\pm}$, are the solutions of (29) shown in (31) taking in to account the experimental errors $\pm \delta$ on the observed orbital period variation $T_{b,\text{obs}}$.

Now, in Fig. 1 we report representative results of our numerical analysis on the sample of binary pulsars we choose. In both panels we use the following notation: the black line shows the behavior of the first derivative of the orbital binary period for the $f(R)$-theories of gravity as computed in eq. (25), the blue line represents the observed orbital period variation $T_{b,\text{obs}}$, the red lines give the error band determined by the experimental errors $\pm \delta$; and finally the green line is representative of the $T_{GR}$ orbital period variation computed from the GR. For the binary pulsar system J2129 + 1210C, Fig. 1, the orbital period variation $T_{GR}$, computed from the GR, is included in experimental error band $\pm \delta$, so as the observed orbital period variation $T_{b,\text{obs}}$. Moreover, it is possible to see from Fig. 1 the GR value of $T_{GR}$ is recovered for $f''_0 = 0$ (green square), whilst to justify the difference $\Delta T_{GR}$ between $T_{b,\text{obs}}$ and $T_{GR}$ we have, from the solution of (31), the values shown in Fig. 1 for $f''_{0,\pm}$ (red square) and for $f'_0$ (blue square). In the panel (b) of the Fig. 1 there is reported for J0751 + 1807 the same situation. In this case the $T_{GR}$ is out of the error band determined by the experimental errors $\pm \delta$. It is again possible to see for $f''_0 = 0$ that the GR value of $T_{GR}$ is recovered, but in this case the $f''_0$ values are order of magnitude greater than the one of the well behaved case of J2129 + 1210C.

In Fig. 2 there are shown, for sake of convenience, in logarithmic scale, the absolute values of $f''_0$ reported in Tab. 2 versus the ratio $\frac{T_{b,\text{obs}}}{T_{GR}}$. We must note that for the first six binaries in tables, the ETGs are not ruled out $0.4 < f''_0 < 38$. For those systems we get $0.5 < \frac{T_{b,\text{obs}}}{T_{GR}} < 1.5$, the difference between $T_{GR}$ and $T_{b,\text{obs}}$ can be explained adding a new contribution from the theory of gravity. Instead for most of binaries we have $f''_0$ values that can surely rule out the theory, since taking account of the weak field assumption we obtain $38 < f''_0 < 4 \times 10^7$. From this last values to the first ones, there is a jump of about four up to five order of magnitude on $f''_0$. The origin of these strong discrepancies, perhaps, is due to the extreme assumption we made, to justify the difference between the observed $T_{b,\text{obs}}$ and the predicted $T_{GR}$ using the ETGs.

5 DISCUSSION AND REMARKS

We want point out in this preliminary work that, where the GR theory is not enough to explain the gap between
the data and the theoretical estimation of the orbital decay, there is the possibility to extend the GR theory with a generic f(R)-theory to cover the gap. Here, we simply verify that this possibility exists, but there is need to compute the Post-Keplerian parameters in the f(R)-theory to estimate correctly the masses of the binary systems to constraint correctly the analytic parameters the ETGs. In post-Minkowskian limit of analytic f(R)-gravity models, the quadrupole-radiation depends on the masses of the two bodies, on the orbital parameters and on the analytic parameters of the f(R)-theory as the coefficients $f''_0$ and $f''_e$ of the Taylor expansion. A first result we present is the analytical solution of the quadrupole radiation rate in which it is possible separate the GR contribution and the one due to the f(R)-gravity. We should note that the correction depends on the eccentricity of the orbit and on the orbital period of the binary system, and specifically, the radiation rate is a function of $f''_0$ and $f''_e$. According to eq. (29) we have selected a sample of relativistic binary systems for which the first derivative of the orbital period is observed, we have computed the theoretical quadrupole radiation rate, and finally we have compared it to binary system observations. From Tab. 3 it is seen that the first five systems have masses determined in a manner quite reliable, while for the remaining sample, masses are estimated by requiring that the mass of the pulsar is $1.4 M_\odot$ and, assuming for the orbital inclination one of the usual statistical values ($i = 60^\circ$ or $i = 90^\circ$), and from here comes then the estimate of the mass of the companion star. So a primary cause of major discrepancies, not only for the ETGs, but also for the GR theory, between the variation of the observed orbital period and the predicted effect of emission of gravitational waves, could be a mistake in the estimation of the masses of the system. In addition, other causes may be attributable to the evolutionary state of the system, which, for instance, if it does not consist of two neutron stars may transfer mass from companion to the neutron star. In our sample, there are only five double NS that can be used to test GR and ETGs. Taking into account of the strong hypothesis we made, the extended theory correction to $T_{GR}$ can also include the galactic acceleration term correction Damour and Taylor (1991), Damour and Taylor (1992)). Here, we give a preliminary result about the energy loss from binary systems and we show that, when the nature of the binary systems can exclude energy losses due to trade or loss of matter, then, we can explain the gap between the first time derivative of the observed orbital period and the theoretical one predicted by GR, using an analytical f(R)-theory of gravity. In conclusion, to improve the estimation of the f(R)-coefficients, we need: to consider the hydrodynamic effects due to the transfer of the matter in the binary system, in order to analyze different systems from double NS; and to improve the estimations of the mass of the stars in the binary systems without prior on pulsar mass and orbital inclination.

*Note:* The Table 1 provides data for binary relativistic pulsars, including the J-Name of the binary pulsar system, the orbital binary period $T_b$ in days, the orbital projected semi-major axis $a \sin i$ in light second, the orbital eccentricity $\epsilon$, the observed orbital period variation $\dot{T}_{\text{obs}}$, the predicted $\dot{T}_{\text{GR}}$ according to the General Relativity theory, the experimental error $\pm \delta$ on $\dot{T}_{\text{obs}}$, and the masses $m_p$ and $m_c$ of the binary system components in solar mass unit.
Table 2. Upper Limits of $f''_0$ correction to $\dot{T}_{GR}$ of binary relativistic pulsars assuming that all the loss of energy is caused by Gravitational Wave emission. We reported the J-Name of the system, the difference $\Delta \dot{T}_{GR}$ between $\dot{T}_{Obs}$ and $\dot{T}_{GR}$ equal to the correction $-f''_0 \dot{T}_b(f(R))$, the correction $\dot{T}_b(f(R))$, the corresponding $f''_0$ solution of (29) shown in (31), the interval centered on $f''_0$ and computed from the difference $\frac{f''_0+\delta -f''_0-\delta}{2}$, where $f''_0 \pm \delta$, are the solutions of (29) shown in (31) taking account of the experimental errors $\pm \delta$ on the observed orbital period variation $\dot{T}_{Obs}$.

Testing $f(R)$-theories using the first time derivative of the orbital period of the binary pulsars

Figure 1. We report representative results of our numerical analyses on the sample of binary pulsars we have selected. In both figures we use the following notation: the black line shows the behavior of the first derivative of the orbital binary period for the $f(R)$-theory of gravitation as computed in eq. (28); the blue line represents the observed orbital period variation $\dot{T}_{b}$; the red lines give the error band determined by the experimental errors $\pm \epsilon$; and finally the green line is representative of the $\dot{T}_{GR}$ orbital period variation computed from the GR. In the panel (a) for the system J2129+1210 C the $\dot{T}_{GR}$ is included in the error band determined by the experimental errors $\pm \delta$, so as $\dot{T}_{b}$. We point out the GR value of $\dot{T}_{GR}$ is recovered for $f''(r) = 0$ (green square), while to justify the difference between $\dot{T}_{b}$ and $\dot{T}_{GR}$ we show the value of $f''(0)$ (blue square) and its error band $f''(0) \pm \delta$ (red square) as computed in eqs. (31) and (32). In the last panel (b) there are reported for J0751+1807 the same data but in this case the $\dot{T}_{GR}$ is OUT of the error band determined by the experimental errors $\pm \delta$. It is possible to see for $f''(0) = 0$ that the GR value of $\dot{T}_{GR}$ is recovered, but in this case the $f''(0)$ values are much greater than the previous ones.
Figure 2. In figure there are shown, for sake of convenience, in logarithmic scale, the absolute values of $f''_0$ reported in Tab. 2 versus the ratio $\frac{T_{b,\text{Obs}}}{T_{GR}}$. We must note that for five binaries the ETGs we are probing is not ruled out $0.04 \leq f''_0 \leq \approx 38$, for those systems the difference between $T_{GR}$ and $T_{b,\text{Obs}}$ is tiny, indeed we get $0.5 \leq \frac{T_{b,\text{Obs}}}{T_{GR}} \leq 1.5$. Instead for most of binaries we have $f''_0$ values that can surely rule out the theory, since taking account of the weak field assumption we obtain $38 \leq f''_0 \leq 4 \times 10^7$. From this last values to the first ones, there is a jump of about four up to five order of magnitude on $f''_0$.
