Introduction.— Strangeness has played a crucial role in the experimental and theoretical investigations of the deconfined phase, namely the Quark Gluon Plasma (QGP) phase, of Quantum Chromodynamics (QCD) at high temperatures. Experimental results from the Relativistic Heavy Ion Collider and the Large Hadron Collider suggest that the QGP has been created during the highly energetic collisions of heavy nuclei [2]. Experimental results showing enhanced production and large collective flow of strange hadrons [3] strongly indicate that deconfined strange quarks existed inside the QGP, despite the absence of real strange quarks within the initially colliding nuclei. However, theoretical understanding of the deconfinement of strangeness remains unclear. A-priori it is not unreasonable to expect that the heavier strange quark may not be largely influenced by the chiral symmetry of QCD and the deconfinement of the strange quarks may not take place at the chiral crossover temperature ($T_c$). Based on the observations that, compared to the light up and down quarks, the net strange quark number fluctuations [4,5] show a much smoother behavior across the chiral crossover region, it has been suggested [4] that the deconfinement crossover for the strange quarks may take place at a temperature larger than $T_c$. Consequently strange hadronic bound states may exist inside the QGP for temperatures $T \gtrsim T_c$ [7].

Moreover, the nature of the deconfined QGP for moderately high temperatures also remains elusive. An intriguing open question is whether in this temperature regime the QGP is a strongly coupled medium lacking a quasi-particle description [2] or consists of other degrees of freedom such as colored bound states [8] or massive colored quasi-particles [9]. Knowledge regarding the behavior of strangeness carrying Degrees of Freedom (sDoF) in the QGP is essential to answer this question.

It is well known [10,11] that the quantum numbers, such as the baryon number ($B$), electric charge ($Q$) and strangeness ($S$), can be probed using the fluctuations and correlations of these quantities. We construct observables from combinations of up to fourth order cumulants of net strange quark number fluctuations and their correlations with net baryon number and electric charge fluctuations, obtained from lattice QCD calculations, have been used to probe the strangeness carrying degrees of freedom at high temperatures. For temperatures up to the chiral crossover separate contributions of strange mesons and baryons can be well described by an uncorrelated gas of hadrons. Such a description breaks down in the chiral crossover region, suggesting that the deconfinement of strangeness takes place at the chiral crossover. On the other hand, the strangeness carrying degrees of freedom inside the quark gluon plasma can be described by a weakly interacting gas of quarks only for temperatures larger than twice the chiral crossover temperature. In the intermediate temperature window these observables show considerably richer structures, indicative of the strongly interacting nature of the quark gluon plasma.

For an uncorrelated gas of hadrons, e.g. the Hadron Resonance Gas (HRG) model [12], the dimensionless partial pressure, $P_S \equiv (p - p_{S=0})/T^4$, of all the strange hadrons is given by

$$P_{S_{HRG}}(\tilde{\mu}_B, \tilde{\mu}_S) = P_{S_{HRG}}^{\tilde{\mu}=1, M_{\tilde{\mu}} = 0} \cosh(\tilde{\mu}_S) + P_{S_{HRG}}^{\tilde{\mu}=1, B_{\tilde{\mu}} = 0} \cosh(\tilde{\mu}_B - \tilde{\mu}_S) + P_{S_{HRG}}^{\tilde{\mu}=1, B_{\tilde{\mu}} = 2} \cosh(\tilde{\mu}_B - 2\tilde{\mu}_S) + P_{S_{HRG}}^{\tilde{\mu}=1, B_{\tilde{\mu}} = 3} \cosh(\tilde{\mu}_B - 3\tilde{\mu}_S) , \quad (1)$$

within the classical Boltzmann approximation. In the temperature range $130 \text{ MeV} \lesssim T \lesssim 200 \text{ MeV}$ relevant for our discussion the Boltzmann approximation gives at most 3% corrections to the full HRG model results for all the susceptibilities involving strangeness considered here and hence is well justified. Here $\mu_B/S = \mu_B/S/T$.
are the dimensionless baryon and strangeness chemical potentials. \( P^{HRG}_{|S|} \) is the partial pressure of all \(|S| = 1\) mesons and \( P^{HRG}_{|S|} \) are the partial pressures of all \(|S| = i \) (\(i = 1, 2, 3\)) baryons, for \(\mu_B = \mu_S = 0\). For simplicity, we have set the electric charge chemical potential \(\hat{\mu}_Q = 0\).

To investigate the sDoF we will use the dimensionless generalized susceptibilities of the conserved charges

\[
\chi^{XY}_{mn} = \left. \frac{\partial^{(m+n)} (\hat{p} \mu_X, \hat{p} \mu_Y)/T^4}{\partial \hat{p}^{(m)}_Y \partial \hat{p}^{(n)}_Y} \right|_{\hat{\mu} = 0},
\]

where \( X, Y = B, S, Q \) and \( \hat{\mu} = (\mu_B, \mu_S, \mu_Q) \). We also use the notations \( \chi^{XY}_{0n} = \chi^n_Y \) and \( \chi^{XY}_{mn} = \chi^m_X \).

Using the two strangeness fluctuations \( (\chi^S_2, \chi^S_4) \) and the four baryon-strangeness correlations \( (\chi^B_1, \chi^S_1, \chi^B_2, \chi^S_2) \) up to fourth order, we have a set of six susceptibilities that can be used to construct observables that project onto the four different partial pressures in an uncorrelated hadrons gas introduced in Eq. (1).

\[
M(c_1, c_2) = \chi^S_2 - \chi^B_2 + c_1 v_1 + c_2 v_2 ,
\]

\[
B_1(c_1, c_2) = \frac{1}{2} (\chi^S_4 - \chi^S_2 + 5\chi^B_1 + 7\chi^B_2)
  + c_1 v_1 + c_2 v_2 ,
\]

\[
B_2(c_1, c_2) = -\frac{1}{4} (\chi^S_4 - \chi^S_2 + 4\chi^B_1 + 4\chi^B_2)
  + c_1 v_1 + c_2 v_2 ,
\]

\[
B_3(c_1, c_2) = \frac{1}{18} (\chi^S_4 - \chi^S_2 + 3\chi^B_1 + 3\chi^B_2)
  + c_1 v_1 + c_2 v_2 .
\]

The combination \(c_1 v_1 + c_2 v_2\) spans a two dimensional plane in the 6-dimensional space of susceptibilities on which the partial pressure \( P^S \) vanishes identically when the sDoF are described by a gas of uncorrelated hadrons irrespective of their masses. The two additional free parameters, \(c_1\) and \(c_2\), can thus be used to construct observables that have an identical interpretation in the uncorrelated hadron gas, but differ under other circumstances, for instance in a medium where the sDoF are carried by quark-like quasi-particles. For \(v_1\) and \(v_2\) we choose the following combinations

\[
v_1 = \chi^S_{31} - \chi^B_{11} ,
\]

\[
v_2 = \frac{1}{3} (\chi^S_2 - \chi^S_4) - 2\chi^B_1 - 4\chi^B_2 - 2\chi^S_{31} .
\]

Since in a hadron gas the baryonic sDoF are associated with \(|B| = 1\), the baryon-strangeness correlations differing by even numbers of \(\mu_B\) derivatives are identical, giving \(v_1 = 0\). \(v_2\) can be re-written as the difference of two operators \([7]\) each of which corresponds to the partial pressure of all strange hadrons in an uncorrelated hadron gas, leading to \(v_2 = 0\). Thus, for a classical uncorrelated hadron gas such as the HRG model \(M(c_1, c_2) \to P^{HRG}_{|S| = 1, M}\) and \(B_i(c_1, c_2) \to P^{HRG}_{|S| = i, B} \) (\(i = 1, 2, 3\)), independent of the values of \(c_1\) and \(c_2\). For asymptotically high temperatures, i.e. when the sDoF are non-interacting massless quarks, these observables will generically attain different values for different combinations of \((c_1, c_2)\).

\textbf{Strangeness near the chiral crossover.} — Here we investigate to what extent sDoF are described by an uncorrelated hadron gas in the vicinity of the chiral crossover temperature \(T_c = 154(9)\) MeV \([13]\). The LQCD results for the susceptibilities were obtained for two different lattice spacings \((a)\) corresponding to temporal extents \(N_T = 1/aT = 6\) and \(8\) using \(O(a^2)\) improved gauge and Highly Improved Staggered Quark \([14]\) discretization schemes for \((2 + 1)\) flavor QCD. The up and down quark masses correspond to a Goldstone pion mass of 160 MeV and the strange quark mass is tuned to its physical value. The susceptibilities were measured on \(3000 - 8000\) gauge field configurations, each separated by 10 molecular dynamics trajectories, using 1500 Gaussian random source vectors for each configuration. Further details of the LQCD computations can be found in \([5, 13]\). Although the LQCD results presented here are not obtained in the limit of zero lattice spacing, the effects of continuum extrapolations are known to be quite small for our particular lattice discretization scheme, especially in the strangeness sector \([5]\). This will also be substantiated by the very mild lattice spacing dependence of our results going from the \(N_T = 6\) to the \(N_T = 8\) lattices. Thus we expect that the continuum extrapolated results will not alter the physical picture presented in this paper.
In Fig. 1 we show the LQCD results for the two combinations $v_1$ and $v_2$, defined in Eq. (7) and Eq. (8), that vanish identically in an uncorrelated hadron gas. The LQCD data for these two quantities are consistent with zero up to $T_c$ and show rapid increase towards their non-interacting massless quark gas values above the $T_c$ region. In Fig. 1 we also show the difference between the quadratic ($\chi_2$) and the quartic ($\chi_4$) baryon number fluctuations that also receive contributions from the light up and down quarks. In an uncorrelated gas of baryons the difference $\chi_2 - \chi_4$ also vanishes identically, owing to the fact that all baryon number carrying degrees of freedom are associated with $|B| = 1$. The LQCD results for this quantity are also consistent with such a hadronic description up to $T_c$, showing rapid departures above the $T_c$ region. All these results indicate that till the chiral crossover, the sDoF are in accord with that of the uncorrelated gas of hadrons and such a description breaks down within the chiral crossover region. Since $v_1$ is the analog of $\chi_2 - \chi_4$ in the strange baryon sector, the fact that both quantities have similar temperature dependence shows that the behavior of the sDoF around the chiral crossover region is rather akin to the behavior of degrees of freedom involving the light quarks. Note that the vanishing values of these observables at low temperatures are independent of the mass spectrum of the hadrons, as long as they are uncorrelated and the Boltzmann approximation is well suited. It reflects that the relevant degrees of freedom carry integer strangeness $|S| = 0, 1, 2, 3$ and integer baryon number $|B| = 0, 1$.

In Fig. 2 we study the partial pressures of the strange hadrons using the LQCD results for the four combinations $M(c_1, c_2)$, $B_1(c_1, c_2)$, $B_2(c_1, c_2)$ and $B_3(c_1, c_2)$ (see Eqs. (3-6)), each for three sets of $(c_1, c_2)$. One of the combinations corresponds to $c_1 = c_2 = 0$ and thus represents the basic projection onto a given strangeness sector in an uncorrelated hadron gas. The other two parameter sets for $(c_1, c_2)$ are chosen to produce widely different values for these observables in a non-interacting massless quark gas at asymptotically high temperatures. From Fig. 2 it is obvious that they are identical at low temperatures. Up to $T_c$, independent of $(c_1, c_2)$, these four quantities individually agree with the partial pressures of the $|S| = 1$ mesons and the $|S| = 1, 2, 3$ baryons when one uses the actual vacuum mass spectrum of the strange hadrons in an uncorrelated hadron gas. Specifically, $M(c_1, c_2)$, $B_1(c_1, c_2)$, $B_2(c_1, c_2)$ and $B_3(c_1, c_2)$ reproduce the HRG model results for $P^{HRG}_{|S|=1,M}$, $P^{HRG}_{|S|=1,B}$, $P^{HRG}_{|S|=2,M}$ and $P^{HRG}_{|S|=3,B}$ respectively [17]. As can be seen from the insets of Fig. 2, such a description of the LQCD results breaks down within the $T_c$ region for each of the meson and baryon sector. Above $T_c$, all these quantities show a smooth approach towards their respective non-interacting, massless quark gas values depending on the values of $c_1$ and $c_2$.

**Strangeness in the quark gluon plasma.**—To investigate whether the sDoF in the QGP can be described by weakly interacting quasi-quarks we study correlations of net strangeness fluctuations with fluctuations of net baryon number and electric charge. Such observables were studied in [11-16] for the second order correlations. We extend these correlations up to the fourth order. If the sDoF are weakly/non-interacting quasi-quarks then strangeness $S = -1$ is associated with the fractional baryon number $B = 1/3$ and electric charge $Q = -1/3$ giving

$$\frac{BS}{\lambda_n} = \frac{(-1)^n}{3^n}, \quad \text{and} \quad \frac{QS}{\lambda_n} = \frac{(-1)^{m+n}}{3^m}, \quad (9)$$

where $m, n > 0$ and $m + n = 2, 4$.

In Fig. 3 we show the LQCD results for these ratios scaled by the proper powers of fractional baryonic and
electric charges. The shaded regions at high temperatures indicate the ranges of values for these ratios as predicted for the weakly interacting quasi-quarks from the re-summed Hard Thermal Loop (HTL) perturbation theory at the one-loop order [17], using one-loop running coupling obtained at the scales between $\pi T$ and $4\pi T$. The ratios of the second order correlations $\chi^{S}_{BB}/\chi^{S}_{S}$ and $\chi^{S}_{BQ}/\chi^{S}_{Q}$ are much closer to those expected for weakly interacting quasi-quarks, differing only at a few percent level for $T \sim 1.25 T_c$. Previous LQCD studies [11] [15] [18] also showed similar results, suggesting that sDoF in the QGP can be described by weakly interacting quasi-quarks even down to temperatures very close to $T_c$. However, our results involving correlations of strangeness with higher power of baryon number and electric charge clearly indicate that such a description in terms of weakly interacting quasi-quarks can only be valid for temperatures $T \geq 2T_c$. While the HTL perturbative expansion for ratios involving one derivative of the baryonic/electric charges (i.e. $\chi^{S}_{BB}/\chi^{S}_{S}$ and $\chi^{S}_{BQ}/\chi^{S}_{Q}$, $X = B,Q$) starts differing from the non-interacting quark gas limit at $O(\alpha_s^2 \ln \alpha_s)$ [19], the same for those involving higher derivatives of the baryonic/electric charges (i.e. $\chi^{S}_{3S}/\chi^{S}_{S}$ and $\chi^{S}_{3Q}/\chi^{S}_{Q}$, $X = B,Q$) starts at $O(\alpha_s^{3/2})$ [17], $\alpha_s$ being the strong coupling constant. Thus, the enhancement of the higher order electric charge/baryon-strangeness correlations is probably expected within the regime of validity of the weak coupling expansion. Apart from the charge/baryon-strangeness correlations presented here, at the fourth order there are 3 more susceptibilities involving derivatives with respect to all $B$, $Q$ and $S$, namely $\chi^{S}_{ijk}$ with $i,j,k > 0$ and $i + j + k = 4$. These baryon-charge-strangeness correlations can also be used in a similar manner to simultaneously probe both $B$ and $Q$ associated with the sDoF. We have studied these quantities too and arrived at the same conclusion regarding the validity of the weakly interacting quark gas picture at high temperatures. Also note that the high temperature behavior of the quantities depicted in Fig. 2 reaffirms our conclusion that the weakly interacting quark gas picture can only be valid for $T \geq 2T_c$. For temperatures beyond the validity of the weak coupling expansion, it would be interesting to see whether such enhancements indicate a strongly coupled QGP [20] without quasi-particles or signal the presence of colored bound states [8] and/or density dependent massive quasi-particles [21].

**Conclusions.**— The LQCD results presented in this paper show that till the chiral crossover temperature $T_c$ the quantum numbers associated with the sDoF are consistent with those of an uncorrelated gas of hadrons. Furthermore, up to $T_c$, the partial pressures of the strange mesons and baryons are separately in agreement with those obtained from the uncorrelated hadron gas using vacuum masses of the strange hadrons. Such a hadronic description of the sDoF breaks down in the chiral crossover region. Moreover, the behavior of the sDoF around $T_c$ is quite similar to that involving the light up and down quarks. Altogether, these results suggest that the deconfinement of strangeness seemingly takes place at the chiral crossover temperature. On the other hand, our LQCD results involving correlations of strangeness with higher powers of baryonic and electric charges for $T > T_c$ provide unambiguous evidence that the sDoF in the QGP can become compatible with the weakly interacting quark gas only for $T \geq 2T_c$. For the intermediate temperatures, $T_c \lesssim T \lesssim 2T_c$, strangeness is non-trivially correlated with the baryonic and electric charges indicating that the QGP in this temperature regime remains strongly interacting.
