Abstract

We introduce FlexibleSUSY, a Mathematica and C++ package, which generates a fast, precise C++ spectrum generator for any SUSY model specified by the user. The generated code is designed with both speed and modularity in mind, making it easy to adapt and extend with new features. The model is specified by supplying the superpotential, gauge structure and particle content in a SARAH model file; specific boundary conditions e.g. at the GUT, weak or intermediate scales are defined in a separate FlexibleSUSY model file. From these model files, FlexibleSUSY generates C++ code for self-energies, tadpole corrections, renormalization group equations (RGEs) and electroweak symmetry breaking (EWSB) conditions and combines them with numerical routines for solving the RGEs and EWSB conditions simultaneously. The resulting spectrum generator is then able to solve for the spectrum of the model, including loop-corrected pole masses, consistent with user specified boundary conditions. The modular structure of the generated code allows for individual components to be replaced with an alternative if available. FlexibleSUSY has been carefully designed to grow as alternative solvers and calculators are added. Predefined models include the MSSM, NMSSM, E\(_6\)SSM, USSM, \(R\)-symmetric models and models with right-handed neutrinos.

Keywords: sparticle, supersymmetry, Higgs, renormalization group equations 

PACS: 12.60.Jv 

PACS: 14.80.Ly
1. Program Summary

Program title: FlexibleSUSY

Program obtainable from: http://flexiblesusy.hepforge.org/

Distribution format: tar.gz

Programming language: C++, Wolfram/Mathematica, FORTRAN, Bourne shell

Computer: Personal computer

Operating system: Tested on Linux 3.x, Mac OS X

External routines: SARAH 4.0.4, Boost library, Eigen, LAPACK

Typical running time: 0.06–0.2 seconds per parameter point

Nature of problem: Determining the mass spectrum and mixings for any supersymmetric model. The generated code must find simultaneous solutions to constraints which are specified at two or more different renormalization scales, which are connected by renormalization group equations forming a large set of coupled first-order differential equations.

Solution method: Nested iterative algorithm and numerical minimization of the Higgs potential.

Restrictions: The couplings must remain perturbative at all scales between the highest and lowest boundary condition. FlexibleSUSY assumes that all couplings of the model are real (i.e. CP-conserving). Due to the modular nature of the generated code adaptation and extension to overcome restrictions in scope is quite straightforward.
2. Introduction

Supersymmetry (SUSY) provides the only non-trivial way to extend the space-time symmetries of the Poincaré group, which still has scattering in the resulting quantum theory [1, 2]. This leads many to suspect that SUSY may be realized in nature in some form. In particular supersymmetric extensions of the Standard Model (SM) where SUSY is broken at the TeV scale have been proposed to solve the hierarchy problem [3, 4, 5, 6, 7], allow gauge coupling unification [8, 9, 10, 11, 12] and predict a dark matter candidate which can fit the observed relic density [13, 14]. Such models have also been used for baryogenesis or leptogenesis to solve the matter-anti-matter asymmetry of the universe and have been considered as the low energy effective models originating from string theory.

Detailed phenomenological studies have been carried out for scenarios within the minimal supersymmetric Standard Model (MSSM), for a review see [16]. Such work has been greatly aided by public spectrum generators for the MSSM [17, 18, 19, 21, 21], allowing fast and reliable exploration of the sparticle spectrum, mixings and couplings, which can be obtained from particular choices of breaking mechanism inspired boundary conditions and specified parameters. Beyond the MSSM there are also two public spectrum generators [22, 23, 24, 25, 26] for the next to minimal supersymmetric Standard Model (NMSSM) (for recent reviews see [27, 28]).

None of the fundamental motivations of supersymmetry requires minimality, and specific alternatives to (or extensions of) the MSSM are, for example, motivated by the $\mu$-problem of the MSSM [29]; explaining the family structure (see e.g. [30]) or for successful baryogenesis or leptogenesis (see e.g. [31]). However constructing specialized tools to study all relevant models would require an enormous amount of work. So general tools which can automate this process and produce fast and reliable programs can greatly enhance our ability to understand and test non-minimal realizations of supersymmetry.

Recent experimental developments have also increased the relevancy of such a tool. From the recent 7 TeV and 8 TeV runs at the Large Hadron Collider (LHC) there have been two important developments. Firstly low energy signatures expected from such models, such as the classic jets plus missing transverse energy signature, have not been observed, substantially raising the lower limit on sparticle masses (see e.g. [32, 33]). No other signature of beyond the Standard Model (BSM) physics has been observed, leaving the fundamental questions which motivated BSM physics unanswered. Secondly ATLAS and CMS discovered [34, 35] a light Higgs of 125 GeV, within the mass range that could be accommodated in the MSSM but requiring stops which are significantly heavier than both the direct collider limits and indirect limits that appears in constrained models from the significantly higher limits on first and second generation squarks.

These developments motivate the exploration of non-minimal SUSY models which ameliorate the naturalness problems by raising the tree level Higgs mass, as can happen in the USSM [36, 37, 38], E6SSM [39, 40] and similar models [41], or from other gauge extensions [42, 43]. At the same time they can also motivate models that are developed with a fresh perspective, based on other considerations. In both cases exploration of such models can be aided if it is possible to quickly create a fast spectrum generator. Currently there is only one option for this, a SPheno-like FORTRAN code which can be generated from SARAH [44, 45, 46, 47, 48].

FlexibleSUSY provides a much needed alternative to this with a structure which has been freshly designed to accommodate as general range of models as possible and to be easily adaptable to changing goals and new ideas. FlexibleSUSY is a Mathematica and C++ package which uses SARAH to create a fast, modular C++ spectrum generator for a user specified SUSY model. The generated code structure is designed to be as flexible as possible to accommodate different types
of extensions and due to its modular nature it is easy to modify, add new features and combine with other programs. The generated code has been extensively tested against well known spectrum generators. As well as providing a solution for new SUSY models, the generated MSSM and NMSSM codes offer a modern and fast alternative to the existing public spectrum generators.

In Section 3 we describe the program in more detail and explain our design goals. In Section 4 information on how to download and compile the code may be found along with details on how to get started quickly. In Section 5 we describe how the user can create a new FlexibleSUSY model file. A detailed description of the structure and features of the generated code is then given in Section 6. In Section 7 we describe the various ways the code can be modified both at the meta code level by writing model files and at the C++ code level by modifying the code or adding new modules. Finally in Section 8 we describe detailed comparisons between our generated code and existing public spectrum generators as well as against the SPhe-no-like FORTRAN code which can be created using SARAH.

3. Overview of the program and design goals

To study the properties of SUSY models programs are needed which numerically calculate the pole masses and couplings of the SUSY particles given a set of theory input parameters. The output of these so-called spectrum generators can be transferred to programs which calculate further observables such as branching ratios or the dark matter relic density.

In order to create a spectrum generator the SUSY model must be defined by specifying the gauge group, the field content and mixings as well as the superpotential and the soft-breaking terms. From this information the renormalization group equations, mass matrices, self-energies, tadpole diagrams and electroweak symmetry breaking (EWSB) conditions have to be derived. These expressions must then be combined in a computer program to allow for a numeric calculation of the mass spectrum. In addition most SUSY models require boundary conditions for the model parameters at a low and a high scale. For example in the CMSSM mSUGRA boundary conditions for the soft-breaking parameters are imposed at the gauge coupling unification scale. Furthermore, at the \( Z \) mass scale the CMSSM is matched to the Standard Model, which implies conditions for the gauge and Yukawa couplings. The so defined boundary value problem must be solved numerically until a set of model parameters has been found consistent with all user-supplied boundary conditions.

FlexibleSUSY is a Mathematica and C++ package designed to create a fast and easily adaptable spectrum generator in C++ for any SUSY model. The user specifies the model by giving the superfield content, superpotential, gauge symmetries and mass mixings in form of SARAH model files. The boundary conditions on the model parameters must be specified in a separate FlexibleSUSY.m.in file. Based on this information FlexibleSUSY uses SARAH to obtain tree-level expressions for the mass matrices and electroweak symmetry breaking conditions, one-loop self energies, one-loop tadpoles corrections and two-loop renormalization group equations (RGEs) for the model. Additional corrections which have been calculated elsewhere, such as two-loop corrections to the Higgs masses may be added by the user. These algebraic expressions are converted into C++ code and are put into classes with well-defined interfaces to allow for easy exchange, extension and reuse of the modules. All of these classes are finally combined to a complete spectrum generator, which solves the

\(^1\)By default FlexibleSUSY has two-loop corrections to the Higgs masses for the MSSM \[49, 54, 51, 52, 53\] and NMSSM \[56\] in FORTRAN files supplied by Pietro Slavich. These are the same corrections which are implemented in many of the public spectrum generators.
user-defined boundary value problem. For this task FlexibleSUSY uses some parts of Softsusy\cite{17}, the very fast Eigen library\cite{62}, augmented by LAPACK, as well as the GNU scientific library and the Boost library to create numerical routines which solve the RGEs and boundary conditions simultaneously. If a solution has been found the pole mass spectrum is eventually calculated using full one-loop self-energies (and leading two-loop Higgs self-energy contributions for the MSSM and NMSSM).

The standard input and output of the generated spectrum generator is the SLHA format\cite{63,64}, which is intended for the communication between MSSM and NMSSM spectrum generators and observable calculators. The user has control over the SLHA block names by editing the SARAH model files and may also add extra blocks in the FlexibleSUSY model file, as described in Section 5. Internally, FlexibleSUSY uses the SLHAea library\cite{54} to read and write the SLHA files. The internally stored SLHAea object can be passed to other programs at the C++ level for inter program communication. We have tested that the HDECAY 3.4\cite{55} and SDECAY 1.4\cite{56}, which are shipped with SUSY-HIT\cite{57}, understand the SLHA output of FlexibleSUSY and give matching output to that from Softsusy. For models which go beyond the MSSM and NMSSM no fixed standard exists which specifies the spectrum generator input and output format. For this reason, FlexibleSUSY allows the user to control the SLHA input and output blocks in order to simplify the process of passing the output of a custom FlexibleSUSY-generated spectrum generator to any private or new public tool developed for that model.

3.1. Design goals

Since the calculation of the pole mass spectrum in a SUSY model is a non-trivial task, FlexibleSUSY is designed with the following points in mind:

Modularity. The large variety of supersymmetric models and potential investigations makes it likely that the user wants to modify the generated spectrum generator source code or reuse components in further programs. FlexibleSUSY offers two levels to influence the code: (i) On the Mathematica model file level the model itself or GUT/weak scale boundary conditions as well as input and output parameters can be controlled (see Section 4.3 and Section 7.1 for examples). (ii) In particular FlexibleSUSY uses C++ object orientation features to modularize the source code so that it is sharply divided into building blocks performing distinct duties. This modular architecture makes it easy for the user to modify, reuse, replace or extend the individual components (see Section 7.2 for examples). An important application of this concept are the boundary conditions, for which the C++ level offers a wider range of possibilities. The boundary conditions solver provides a plugin mechanism via a common constraint interface, which allows a user to exchange or add boundary conditions at any scale. To realize this, all (derived) constraint objects are intentionally kept outside the solver. Despite being independent of one another, they can fit together with the aid of class inheritance. An elaborate example of a tower of effective field theories and multiple matching scales is presented in Section Appendix A.1. Alternatively, the modular structure makes it straightforward to take FlexibleSUSY generated code for e.g. RGEs or self-energies and reuse it in an existing code for some other purpose. Conversely, it is also easy to include code from elsewhere into the spectrum generator. For an example see Section Appendix A.2.

Speed. Exploring the parameter space of supersymmetric models with a high number of free parameters is quite time consuming. Therefore FlexibleSUSY aims to produce spectrum generators with a short run-time. The two most time consuming parts of a SUSY spectrum generator are usually the calculation of the two-loop $\beta$-functions and the pole masses of mixed particles:
• **Calculation of the β-functions:** The RG solving algorithms usually need \(O(10)\) iterations between the high and the low scale to find a set of parameters consistent with all boundary conditions with a 0.01\% precision goal. During each iteration the Runge-Kutta algorithm needs to calculate all β-functions \(O(50)\) times. Most two-loop β-functions involve \(O(50)\) matrix multiplications and additions. All together one arrives at \(O(10^4)\) matrix operations. To optimize these, FlexibleSUSY uses the fast linear algebra package [http://eigen.tuxfamily.org](http://eigen.tuxfamily.org). Eigen uses C++ expression templates to remove temporary objects and enable lazy evaluation of the expressions. It supports explicit vectorization, and provides fixed-size matrices to avoid dynamic memory allocation. All of these features in combination result in very fast code for the calculation of the β-functions in FlexibleSUSY.

• **Calculation of the pole masses:** The second most time consuming part is the precise calculation of the pole masses for mixed particles. For each particle \(\psi_k\) in a multiplet the full self-energy matrix \(\Sigma_{ij}^{\psi}(\rho = m_{\text{tree}}^{\psi_k})\) has to be evaluated. Each self-energy matrix entry again involves the calculation of \(O(50)\) Feynman diagrams, each involving the calculation of vertices and a loop-function. All in all, one arrives at \(O(500)\) Feynman diagrams and \(O(10^4)\) loop function evaluations. To speed up the calculation of the pole masses FlexibleSUSY makes use of multi-threading, where each pole mass is calculated in a separate thread. This allows the operating system to distribute these calculations among different CPU cores. With this technique one can gain a speed-up of 20–30\%.

*Alternative boundary value problem solvers.* Furthermore, the standard algorithm which solves the user-defined boundary value problem via a fixed-point iteration is not guaranteed to converge in all regions of the model parameter space. Therefore, FlexibleSUSY has been intentionally designed to allow for alternative solvers to search for solutions in such critical parameter regions. A subsequent release with an alternative solver is already planned.

*Towers of effective theories.* In FlexibleSUSY the standard fixed-point iteration solver has been generalized to handle towers of models (effective theories), which are matched at intermediate scales. An example of such a tower construction will be given in Section Appendix A.1 where right-handed neutrinos are integrated out at the see-saw scale, between the SUSY and the GUT scale.

3.2. **Current limitations and future extensions**

Although we try to handle as many models as possible, there are still some limitations to what can be done. In its current form FlexibleSUSY assumes all couplings are real, therefore it is limited to \(C.P\)-conserving versions of SUSY models. Although it is implicit in the title, we would like to stress that currently we cannot provide a spectrum generator for non-SUSY models. This also means that like other spectrum generators it is difficult to reliably predict the mass spectrum in extreme cases such as Split-SUSY [58, 59, 60], where the mass scales of the SUSY model are drastically split, leading to very large logarithms which are not resummed. In such cases the tower of effective theories offers the best possibility for a solution. However, for this to work FlexibleSUSY must be extended to include non-SUSY models. Finally, the gauge group of the model is currently restricted to be semi-simple and to contain the Standard Model gauge group as factor, so that the SUSY model can be directly matched to the SM at low energies. Future releases which extend FlexibleSUSY beyond each of these limitations are already planned.
4. Quick start

4.1. Requirements

FlexibleSUSY can be downloaded from [http://flexiblesusy.hepforge.org](http://flexiblesusy.hepforge.org). To create a custom spectrum generator the following requirements are necessary:

- Mathematica, version 7 or higher
- SARAH, version 4.0.4 or higher [http://sarah.hepforge.org](http://sarah.hepforge.org)
- C++11 compatible compiler (g++ 4.4.7 or higher, clang++ 3.1 or higher, icpc 12.1 or higher)
- FORTRAN compiler (gfortran, ifort etc.)
- Eigen library, version 3.1 or higher [http://eigen.tuxfamily.org](http://eigen.tuxfamily.org)
- Boost library, version 1.37.0 or higher [http://www.boost.org](http://www.boost.org)

Optional:

- Looptools, version 2.8 or higher [http://www.feynarts.de/looptools](http://www.feynarts.de/looptools)

4.2. Downloading FlexibleSUSY and generating a first spectrum generator

FlexibleSUSY can be downloaded as a gzipped tar file from [http://flexiblesusy.hepforge.org](http://flexiblesusy.hepforge.org). To download and install version 1.0.3 run:

```
$ wget https://www.hepforge.org/archive/flexiblesusy/FlexibleSUSY-1.0.3.tar.gz
$ tar -xf FlexibleSUSY-1.0.3.tar.gz
$ cd FlexibleSUSY-1.0.3
```

A CMSSM spectrum generator can be created with the following three commands:

```
$ ./createmodel --name=MSSM
$ ./configure --with-models=MSSM
$ make
```

The first command creates the model directory `models/MSSM/` together with a CMSSM model file accompanied by a specimen SLHA input file. The configure script checks the system requirements and creates the Makefile. See `./configure --help` for more options. Executing `make` will start Mathematica to generate the spectrum generator and compile it. The resulting executable can be run like this:

```
$ cd models/MSSM
$ ./run_MSSM.x --slha-input-file=LesHouches.in.MSSM
```
When executed, the spectrum generator tries to find a set of DR model parameters consistent with all CMSSM boundary conditions for the parameter point given in the SLHA input file LesHouches.in.MSSM. Afterwards, the pole mass spectrum and mixing matrices are calculated and written to the standard output in SLHA format [63, 64]. For the parameter point given in the above example the calculated pole mass spectrum reads

### 4.3. Spectrum generators for alternative models

FlexibleSUSY already comes with plenty of predefined models: the CMSSM (simply called MSSM), the NMSSM in its $Z_3$-symmetric form (called NMSSM), $Z_3$-violating NMSSM (SMSSM), the USSM (UMSSM), the NUHM $E_6$SSM (E$6$SSM) [65], the right-handed neutrino extended MSSM (MSSMRHN), the NUHM-MSSM (NUHMSSM) and the $R$-symmetric MSSM (MRSSM) [66]. See the content of model_files/ for all predefined model files. For all these models spectrum generators can be generated easily like for the CMSSM in Section 4.2. The spectrum generator for the $Z_3$-symmetric NMSSM for example can be generated like this:

```
$ ./createmodel --name=NMSSM
$ ./configure --with-models=NMSSM
```
One of the design goals is modularity and the possibility to easily construct custom spectrum generators. The details of the customization can be found in Sections 5–7. As a simple example consider the NMSSM. The NMSSM variant above unifies all soft-breaking trilinear scalar couplings at the GUT scale. In order to relax this constraint and use a separate value for $A_\lambda$ at the GUT scale one can edit the model file `model_files/NMSSM/FlexibleSUSY.m.in` and change the lines

```
EXTPAR = { {61, LambdaInput} };  
HighScaleInput = {   
    ...   
    {{Lambda}, Azero LambdaInput},   
    ...   
};
```

into

```
EXTPAR = { {61, LambdaInput},   
            {63, ALambdaInput} };  
HighScaleInput = {   
    ...   
    {{Lambda}, ALambdaInput LambdaInput},   
    ...   
};
```

The value of $A_\lambda$ at the GUT scale can then be set in the SLHA input file in the `EXTPAR` block entry 63 via

```
Block EXTPAR   
  61    0.1    # LambdaInput   
  63   -100    # ALambdaInput
```

5. Setting up a FlexibleSUSY model

A general (non-constrained) softly broken SUSY model is defined by the gauge group, the field content and mixings as well as the superpotential and the soft-breaking Lagrangian. In order to create a spectrum generator for such a SUSY model with FlexibleSUSY, the aforementioned model properties have to be defined in a SARAH model file. The SARAH model file can be put into the `sarah/<model>/` directory. See the SARAH manual \[67,48\] for a detailed explanation of how to write such a model file. Note that SARAH already is distributed with a lot of predefined models, which can be used with FlexibleSUSY immediately.

The model boundary conditions are defined in the FlexibleSUSY model file `FlexibleSUSY.m`, which has to be located in the model directory `models/<model>/`. To add this the user should create a `FlexibleSUSY.m.in` file in the directory `model_files/<model>/`. When the `./createmodel` script is executed, the `FlexibleSUSY.m` file is created from the `model_files/<model-file-name>/FlexibleSUSY.m.in` file, where the directory `<model-file-name>` is specified by the `--model-file=<model-file-name>` option.
If no such option is given the directory matching the \texttt{--name=<model>} option is used. In either case the \texttt{FlexibleSUSY.m} file which is created is then automatically placed in the directory \texttt{models/<model>/}. Note that many predefined example model files can already be found in \texttt{model_files/}.

In the following it is explained how the boundary conditions can be defined on the basis of the CMSSM. The application to other models is straightforward. The CMSSM model file reads:

```plaintext
FSModelName = "@CLASSNAME@";

The first line `FSModelName = "@CLASSNAME@";` will be replaced with `FSModelName = "<model>";` in the generated `FlexibleSUSY.m` file, where `<model>` is specified by the `--name=<model>` option for the `/createmodel` script. So the variable `FSModelName` then contains the name of the FlexibleSUSY model.

All non-Standard Model input variables must be specified in the lists `MINPAR` and `EXTPAR`. These two variables refer to the MINPAR and EXTPAR blocks in a SLHA input file [63]. The list elements are two-component lists where the first entry is the SLHA index in the MINPAR or EXTPAR block, respectively, and the second entry is the name of the input parameter. In the above example the input parameters are the universal soft-breaking parameters $m_0$, $M_1/2$, $A_0$ as well as $\tan \beta$ and `sign \mu`.

Using the variable `EWSBOutputParameters` the user can specify the model parameters that are output of the electroweak symmetry breaking consistency conditions. When imposing the EWSB, FlexibleSUSY will adjust these parameters until the EWSB conditions are fulfilled. In the CMSSM example above these are the superpotential parameter $\mu$ and its corresponding soft-breaking parameter $B\mu$. In the NMSSM the parameters $\kappa$, $|v_s|$ and $m_2^s$ are usually chosen for this purpose.

Furthermore, the user has to specify three model constraints: low-scale, SUSY-scale and high-scale. In FlexibleSUSY they are named as `LowScale`, `SUSYScale` and `HighScale`. For each constraint there is (i) a scale definition (named after the constraint), (ii) an initial guess for the scale (concatenation of the constraint name and `FirstGuess`) and (iii) a list of parameter settings to be applied at the scale (concatenation of the constraint name and `Input`). Optionally a minimum and a maximum value for the scale can be given (concatenation of the constraint name and `Minimum` or `Maximum`, respectively). The latter avoids underflows or overflows of the scale value during the iteration. This is especially useful in models where the iteration is very unstable and the value of the scale is very sensitive to the model parameters. The meaning of the three constraints is the following:

- **High-scale constraint:** The high-scale constraint is usually the GUT-scale constraint, imposed at the scale where the gauge couplings $g_1$ and $g_2$ unify. The high-scale can be defined by an equation of the form $g_1 = g_2$ or by a fixed numerical value. Note that FlexibleSUSY GUT-normalizes all gauge couplings. Thus, the high-scale definition takes the simple form $g_1 = g_2$. As a consequence in the calculation of the VEVs $v_u$ and $v_d$ from $M_Z$ and $\tan \beta$ at the low-scale the GUT-normalization has to be taken into account, see the example above.

- **SUSY-scale constraint:** The SUSY-scale is the typical mass scale of the SUSY particle spectrum. At this scale FlexibleSUSY imposes the EWSB conditions and calculates the pole mass
The SUSY-scale, $M_S$, is defined as

$$M_S = \sqrt{\prod_{i=1}^{6} |m_\ell_i|^2 + |(Z_u)_{i6}|^2},$$  

where $m_\ell_i$ is the DR mass of the $i$th up-type squark and $Z_u$ is the up-type squark mixing matrix. The definition (1) is equivalent to the usual choice $M_S = \sqrt{m_{\tilde{t}_1} m_{\tilde{t}_2}}$ without squark flavour mixing.

- **Low-scale constraint**: The low-scale constraint is the constraint where the SUSY model is matched to the Standard Model. This is done by automatically calculating the gauge couplings $g_i (i = 1, 2, 3)$ of the SUSY model from the known Standard Model quantities $\alpha_{\text{em}}(M_Z)$, $\alpha_s(M_Z)$, $M_Z$, $M_W$. The details of this calculation are explained in Section 6.2.1. Currently this scale is fixed to be the $Z$ pole mass scale $M_Z$. Optionally the Yukawa couplings $y_f (f = u, d, e)$ can be calculated automatically from the known Standard Model fermion masses $m_f$ by setting their values to Automatic. This automatic calculation is explained in Section 6.2.2.

The variables LowScaleInput, SUSYScaleInput and HighScaleInput, which list the parameter settings for imposing the constraints can contain as elements any of the following:

- Two-component lists of the form (parameter, value), which indicates that the parameter is set to value at the defined scale. If the value should be read from the SLHA input file, it must be written as LHInput[value]. Example:

```
SUSYScaleInput = {
    {mHd2, m0^2},
    {mHu2, LHInput[mHu2]}
};
```

In this example the parameter mHd2 is set to the value of m0^2, and mHu2 is set to the value given in the SLHA input file in block MSFIFTYN, entry 22 at the SUSY scale. The SLHA block names and keys for the MSSM and NMSSM are defined in SARAH’s parameters.m file, see the SARAH manual or [46]. For the Standard Model Yukawa couplings $\bar{u}$, $\bar{d}$, $\bar{e}$ the value Automatic is allowed, which triggers their automatic determination from the known Standard Model quark and lepton masses, see Section 6.2.2.

- The function FSMinimize[parameters, function] can be given, where parameters is a list of model parameters and function is a function of these parameters. FSMinimize[parameters, function] will numerically vary the parameters until the function is minimized. Example:

```
FSMinimize[{{vd, vu},
    (SM[MZ] - Pole[M[VZ]])^2 / STANDARDDEVIATION[MZ]^2 +
    (SM[MH] - Pole[M[hh[1]]])^2 / STANDARDDEVIATION[MH]^2}
```

Here, the parameters $v_d$ and $v_u$ are varied until the function

$$\chi^2(v_d, v_u) = \frac{(\text{SM}[\text{MZ}] - m_{\text{pole}})^2}{\sigma^2_{m_{\text{Z}}}} + \frac{(\text{SM}[\text{MH}] - m_{\text{pole}})^2}{\sigma^2_{m_{\text{H}}}}$$

(2)
is minimal. The constants $SM[M_Z]$, $SM[M_H]$, $\sigma_{m_Z}$ and $\sigma_{m_h}$ are defined in src/ew_input.hpp to be

$$SM[M_Z] = 91.1876, \quad SM[M_H] = 125.9,$$

$$\sigma_{m_Z} = 0.0021, \quad \sigma_{m_h} = 0.4.$$  

(3) (4)

- The function `FSFindRoot(parameters, functions)` can be given, where `parameters` is a list of model parameters and `functions` is a list of functions of these parameters. `FSFindRoot(parameters, \ functions)` will numerically vary the parameters until the functions are zero. Example:

```csharp
FSFindRoot[{vd,vu},
```

Here, the parameters $v_u$ and $v_d$ are varied until the vector-valued function

$$f(v_d, v_u) = \left( \frac{SM[MZ] - m_{Z}^{pole}}{SM[MH] - m_{h_1}^{pole}} \right)$$

is zero.

Finally, the user can set an initial guess for the model parameters at the low- and high-scale using the variables `InitialGuessAtLowScale` and `InitialGuessAtHighScale`, respectively. The gauge couplings will be guessed automatically at the low-scale from the known Standard Model parameters.

FlexibleSUSY allows the user to add leading two-loop contributions to the $CP$-even and $CP$-odd Higgs self-energies as well as to the $CP$-even Higgs tadpoles. For MSSM-like models (with two $CP$-even Higgs bosons, one $CP$-odd Higgs boson, one neutral Goldstone boson) routines for calculating these corrections will be generated by setting `UseHiggs2LoopMSSM = True` in the model file and by defining the effective $\mu$-term `EffectiveMu = \[Mu\]`. This will add the zero-momentum corrections of the order $O(y_t^4 + y_b^2 y_t^2 + y_b^4)$, $O(y_t^2 y_b^2)$, $O(y_t^2 y_b^2)$, $O(y_t^4)$ from [49, 50, 51, 52, 53]. For NMSSM-like models (with three $CP$-even Higgs bosons, two $CP$-odd Higgs bosons, one neutral Goldstone boson) the two-loop contributions are generated by setting `UseHiggs2LoopNMSSM = True` and by defining the effective $\mu$-term like `EffectiveMu = \[Lambda\] vS / Sqrt[2]`, for example. This will add the zero-momentum corrections of the order $O(y_t^2 y_b^2)$, $O(y_t^2 y_b^2)$ from [61] and also the MSSM contributions of the order $O(y_t^4)$, $O(y_t^4 + y_t^2 y_b^2 + y_b^4)$ as well [54, 52] which only represent a partial correction for that order in the NMSSM, but can be a good approximation when singlet mixing is very small.\footnote{These corrections may be disabled in the SLHA file, as described in section Section 6.5.}

The corrections can then be used in the calculation of the Higgs masses, when appropriate settings are selected in the SLHA file. Note that even in the NMSSM the user must make an important decision as to whether or not to enable the generated MSSM corrections which are incomplete in the NMSSM. We feel that it is valuable to have these MSSM corrections for scenarios where singlet mixing is very small and in particular for cross checks against the MSSM when close to the MSSM limit of the model. However in cases where the singlet mixing is large the result at $O(y_t^4 + y_t^2 y_b^2 + y_b^4)$ and $O(y_t^4)$ will not be complete and including these corrections could in principle even make the numerical result further away from the correct two loop result at that order if there is a cancellation with the missing contributions. So while including such partial two-loop

\textcopyright 15
corrections does not change the formal accuracy the user should choose whether or not to include these corrections based on the physics they study. Similarly in models that go beyond the NMSSM the user must decide based on the physics whether or not these corrections will give the leading two-loop corrections in their model.

One can create a pure low-energy model by setting `OnlyLowEnergyFlexibleSUSY = True`. In this case the high-scale constraint is ignored and only the low-scale and SUSY-scale constraints are used. All model parameters which are not specified in `MINPAR` or `EXTPAR` will then be read from the corresponding input blocks in the SLHA input file and will be set at the SUSY-scale. An example of such a pure low-energy model is the MRSSM, where the three gauge couplings do not unify at a common scale.

FlexibleSUSY can create the helper function `get_lsp()`, which finds the lightest supersymmetric particle (LSP). To have this function be created the model file variable `PotentialLSPParticles` must be set to a list of SUSY particles which are potential LSPs. In the model file example above, the particles Chi, Cha, Glu, Sv, Su, Sd, Se (neutralino, chargino, gluino, sneutrino, up-type squark, down-type squark, selectron) are considered to be LSP candidates.

Finally, with the variable `ExtraSLHAOutputBlocks` the user can define extra SLHA output blocks. The values of the block entries will be calculated at the output scale, which is specified in entry 12 in the SLHA input block `MODSEL`. In the example model file above the following six extra SLHA compliant output blocks are defined: `ALPHA`, `HMIX`, `Au`, `Ad`, `Ae` and `MSOFT`. The `ALPHA` output block contains the $\mu$-parameter, the ratio $\tan \beta = v_u/v_d$, the combination $v = \sqrt{v_u^2 + v_d^2}$, the squared mass of the $CP$-odd Higgs $m_A^2$, the soft-breaking parameter $B\mu$ and the values of $v_u$ and $v_d$, all defined in the $\overline{DR}$ scheme. In an analogous way four more output blocks for the soft-breaking $\overline{DR}$ parameters are defined. For a CMSSM example parameter point with $m_0 = 125$ GeV, $M_{1/2} = 500$ GeV, $\tan \beta = 10$, sign $\mu = +1$ and $A_0 = 0$ the FlexibleSUSY-generated CMSSM spectrum generator writes the so defined blocks to the output in the form

```

### 6. Structure of the spectrum generator

In this section we explain the internals of FlexibleSUSY’s automatically generated spectrum generator.

As mentioned in Section 3, FlexibleSUSY uses SARAH-generated expressions for the $\beta$-functions, mass matrices, self-energies and EWSB conditions plus the user-defined parameter boundary conditions to create a spectrum generator in C++. This program takes the Standard Model and user-defined input parameters and numerically solves the boundary value problem, which is defined by the RG equations and the boundary conditions. If a solution is found the pole mass spectrum is calculated.

In the following it is explained how this procedure is realized in FlexibleSUSY. As mentioned in Section 3 one of FlexibleSUSY’s design goals is to create modular C++ code to allow for an easy exchange, extension and reuse of the generated modules. For this reason Section 6.1 first of all briefly describes the so-called C++ “model class” hierarchy, which contains the general model information, such as parameters, $\beta$-functions, DR mass spectrum, EWSB, self-energies, and the pole mass spectrum. Section 6.2 describes how boundary conditions on the model parameters are implemented in general at the C++ level. Subsections 6.2.1–6.2.3 then show the two concrete boundary conditions, which are always imposed: The matching of the model parameters to the Standard Model and the electroweak symmetry breaking. In Section 6.3 we describe the conventions used to calculate the DR mass spectrum given a set of DR model parameters. Afterwards, in Section 6.4 the algorithm, which solves the user-defined boundary value problem is described on the basis of the CMSSM example given in Section 5. Finally, Section 6.5 explains how the pole mass spectrum is obtained from the DR model parameters after a solution to the boundary value problem has been found.
6.1. Model parameters and RGEs

The parameters of the model together with their RGEs, mass matrices, self-energies and EWSB equations are stored at the C++ level in the model class hierarchy, which is shown in the UML diagram in Figure 1.

The top of the hierarchy is formed by the Beta_function interface class, which defines the basic RGE running interface. It provides the interface function run_to(), which integrates the RGEs up to a given scale using an adaptive Runge-Kutta algorithm. This algorithm uses the pure virtual functions get(), set() and beta(), which need to be implemented by a derived class. The get() and set() functions return and set the model parameters in form of a vector, respectively. The beta() method returns the β-function for each parameter in form of a vector as well.

All model parameters and their β-functions are contained in the first and second derived classes. The structure of the β-functions of a general supersymmetric model [68, 69, 70, 71, 72, 75, 76, 74, 73, 77, 78, 79, 80] allows to split these parameters into two classes:

1. SUSY parameters: gauge couplings, superpotential parameters and VEVs and
2. soft-breaking parameters: soft linear scalar terms, soft bilinear scalar interactions, soft trilinear scalar interactions, soft quadlinear scalar interactions, soft gaugino mass terms and soft scalar squared masses.

The β-functions of the SUSY parameters in general depend only on the SUSY parameters and are independent of the soft-breaking parameters. However, the β-functions of the soft-breaking parameters depend on all model parameters in general. This property is reflected in the C++ code: The class <model>_susy_parameters directly inherits from Beta_functions and implements the β-functions of the SUSY parameters. The class of soft-breaking parameters <model>_soft_parameters in turn inherits from <model>_susy_parameters and implements the β-functions of the soft-breaking parameters in terms of all model parameters. The so constructed class hierarchy allows to (i) use the RGE running of all model parameters via the common Beta_function interface and to (ii) run the SUSY parameters independently of the soft-breaking parameters.

FlexibleSUSY creates these two classes from the model parameters defined in the SARAH model file. The corresponding one- and two-loop β-functions are calculated algebraically using SARAH’s CalcRGEs() routine, converted to C++ form and written into the corresponding beta() functions. These two classes then allow to use renormalization group running of all model parameters.

At the bottom of the hierarchy stands the actual model class, which uses the DR parameters from the parent classes to calculate DR and pole mass spectra. These two calculations are performed in the calculate_DRbar_masses() and calculate_pole_masses() functions, which make use of the mass matrices and self-energies obtained from SARAH. The calculation of the pole mass spectrum will be explained in detail in Section 6.5. The resulting masses can be obtained by calling get_physical(). The calculate_spectrum() function combines these two spectrum computations into one call. In addition, the model class provides a solve_ewsb() method, which solves the electroweak symmetry breaking equations numerically at the loop level. This function is explained in the next section.

6.2. Boundary conditions

As described in Section 5, the user defines three boundary conditions in the FlexibleSUSY model file at the Mathematica level. These boundary conditions are converted to C++ form and are put into classes, which implement the common Constraint<Two_scale> interface. This interface has the form:
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beta_function</td>
<td>+ get() + set() + beta() + run_to()</td>
</tr>
<tr>
<td>&lt;model&gt;_susy_parameters</td>
<td>- susy parameters + get() + set() + beta() + run_to()</td>
</tr>
<tr>
<td>&lt;model&gt;_soft_parameters</td>
<td>- soft-breaking parameters + get() + set() + beta() + run_to()</td>
</tr>
</tbody>
</table>
| <model>         | - DR masses and mixing matrices + calculate_DRbar_parameters() + calculate_pole_masses() + calculate_spectrum() + get_physical() + solve_ewsble

Figure 1: Model class hierarchy.
The `get_scale()` function is supposed to return the renormalization scale at which the constraint is to be imposed. The `apply()` method imposes the constraint by setting model parameters to values as chosen by the user. The three boundary condition classes are generated as follows:

- **The high-scale constraint** is intended to set boundary conditions on the model parameters at some very high scale, e.g., the GUT scale $M_X$. The high-scale is defined by the value given in the variable `HighScale`. In the CMSSM example model file in Section 5 it is defined to be the unification scale $M_X$ where $g_1(M_X) = g_2(M_X)$. The `apply()` function is implemented by setting model parameters to the values defined in the `HighScaleInput` variable.

- **The SUSY-scale constraint** is intended to set boundary conditions at the mass scale $M_S$ of the SUSY particles. The value of $M_S$ is defined in the model file variable `SUSYScale`. In the example model file in Section 5, it is given by the expression written in Eq. (1). The `apply()` function for this constraint sets the model parameters to the values defined in `SUSYScaleInput`. Afterwards, `apply()` solves the EWSB equations at the loop level by adjusting the parameters given in `EWSBOutputParameters` such that the effective Higgs potential is minimized. See Section 6.2.3 for a more detailed description of the EWSB in FlexibleSUSY.

- **The low-scale constraint** is intended to match the SUSY model to the Standard Model at the scale $M_Z$. It does so by calculating the gauge couplings of the SUSY model from the known Standard Model quantities $\alpha_{e.m.,SM}(M_Z)$, $\alpha_{s,SM}(M_Z)$, $M_Z$ and $M_W$. This calculation is explained in Section 6.2.1. Optionally, the Yukawa couplings of the SUSY model can be calculated automatically from the Standard Model fermion masses. See Section 6.2.2 for more details. In addition to the gauge and Yukawa couplings, the model parameter constraints given in `LowScaleInput` are imposed here.

### 6.2.1. Calculation of the gauge couplings $g_i(M_Z)$

The low-scale constraint matches the SUSY model to the Standard Model. Currently FlexibleSUSY allows only SUSY models with semisimple gauge groups, which contain the Standard Model gauge group $SU(3) \times SU(2) \times U(1)$ as a factor. This enables FlexibleSUSY to directly identify the strong, left-handed and hypercharge gauge couplings $g_i$ ($i = 1, 2, 3$).

The low-scale constraint automatically calculates the DR gauge couplings $g_{i,Susy}(M_Z)$ in the SUSY model at the scale $M_Z$. It starts from the known electromagnetic and strong MS couplings in the Standard Model including only 5 quark flavours $\alpha_{e.m.,SM}(M_Z) = 1/127.944$ and $\alpha_{s,SM}(M_Z) = 0.1185$ [8]. These are converted to the electromagnetic and strong DR couplings in the SUSY
The $\Delta \alpha_i(\mu)$ are threshold corrections and read

\[
\Delta \alpha_{\text{e.m.}, \text{SM}}(\mu) = \frac{\alpha_{\text{e.m.}}}{2\pi} \left[ \frac{1}{3} - \frac{16}{9} \log \frac{m_t}{\mu} \right],
\]

\[
\Delta \alpha_{\text{e.m.}, \text{susy}}(\mu) = \frac{\alpha_{\text{e.m.}}}{2\pi} \left[ - \sum_{\text{susy particle } i} F_i T_i \log \frac{m_i}{\mu} \right],
\]

\[
\Delta \alpha_{\text{s}, \text{SM}}(\mu) = \frac{\alpha_s}{2\pi} \left[ - \frac{2}{3} \log \frac{m_t}{\mu} \right],
\]

\[
\Delta \alpha_{\text{s}, \text{susy}}(\mu) = \frac{\alpha_s}{2\pi} \left[ \frac{1}{2} - \sum_{\text{susy particle } i} F_i T_i \log \frac{m_i}{\mu} \right],
\]

where the sums on the right-hand sides run over all electrically and color charged fields absent from the Standard Model. The constants $T_i$ are the Dynkin indices of the representation of particle $i$ with respect to the gauge group, and $F_i$ are particle-type specific constants [82].

\[
F_i = \begin{cases} 
2/3 & \text{if particle } i \text{ is a Majorana fermion,} \\
4/3 & \text{if particle } i \text{ is a Dirac fermion,} \\
1/6 & \text{if particle } i \text{ is a real scalar,} \\
1/3 & \text{if particle } i \text{ is a complex scalar.}
\end{cases}
\]

Afterwards, the user-defined expression for the Weinberg angle $\theta_W$ in terms of $M_{W, \text{susy}}^{\text{DR}}(M_Z)$ and $M_{Z, \text{susy}}^{\text{DR}}(M_Z)$ (defined by the user in the SARAH model file) is used to calculate $\theta_W$ in the SUSY model in the $\text{DR}$ scheme. In the MSSM, for example, it yields

\[
\theta_{W, \text{susy}}^{\text{DR}}(M_Z) = \arcsin \sqrt{1 - \left( \frac{M_{W, \text{susy}}^{\text{DR}}(M_Z)}{M_{Z, \text{susy}}^{\text{DR}}(M_Z)} \right)^2}.
\]

In a model with a Higgs triplet the relation looks like

\[
\theta_{W, \text{susy}}^{\text{DR}}(M_Z) = \arcsin \sqrt{1 - \left( \frac{M_{W, \text{susy}}^{\text{DR}}(M_Z)}{M_{Z, \text{susy}}^{\text{DR}}(M_Z)} \right)^2 - g_2^2 v^2}.
\]
where \( v_T \) is the vacuum expectation value of the scalar Higgs triplet field. In models with an additional \( U(1)' \) gauge group, the additional \( Z' \) gauge boson can mix with the \( Z \) boson. In such models the Weinberg angle can be defined by parametrizing the \( Z\text{–}Z' \) mixing matrix as

\[
\begin{pmatrix}
\cos \theta_W & -\sin \theta_W & \cos \theta'_W \\
\sin \theta_W & \cos \theta_W & \sin \theta'_W \\
0 & \sin \theta'_W & \cos \theta'_W
\end{pmatrix},
\]

(17)

where \( \theta'_W \) is the \( Z\text{–}Z' \) mixing angle. The running \( \overline{\text{DR}} \) \( W \) and \( Z \) boson masses are calculated in each iteration from the corresponding pole masses as

\[
\left( M_{W, \text{susy}}^{\overline{\text{DR}}}(M_Z) \right)^2 = M_W^2 + \text{Re} \Pi_W^T(p^2 = M_W^2, \mu = M_Z),
\]

(18)

\[
\left( M_{Z, \text{susy}}^{\overline{\text{DR}}}(M_Z) \right)^2 = M_Z^2 + \text{Re} \Pi_Z^T(p^2 = M_Z^2, \mu = M_Z),
\]

(19)

where \( M_W = 80.404 \text{ GeV} \) and \( M_Z = 91.1876 \text{ GeV} \). Having \( \theta_W^{\overline{\text{DR}}}(M_Z) \) and \( \theta'_W^{\overline{\text{DR}}}(M_Z) \) allows to calculate the (GUT-normalized) \( U(1)' \) and \( SU(2)_L \) gauge couplings in the SUSY model. In the MSSM they read for instance

\[
g_{1, \text{susy}}^{\overline{\text{DR}}}(M_Z) = \sqrt{\frac{5}{3} \frac{\text{Re} \Pi_W^{\overline{\text{DR}}}(M_Z)}{\sin \theta_W^{\overline{\text{DR}}}(M_Z)}},
\]

(20)

\[
g_{2, \text{susy}}^{\overline{\text{DR}}}(M_Z) = \sqrt{\frac{2}{3} \frac{\text{Re} \Pi_Z^{\overline{\text{DR}}}(M_Z)}{\sin \theta_W^{\overline{\text{DR}}}(M_Z)}}.
\]

(21)

6.2.2. Calculation of the Yukawa couplings \( y_f(M_Z) \)

The considered SUSY model is required to contain the three generations of Standard Model quarks and leptons. If these particles acquire their masses due to Yukawa interactions with Higgs doublets, then the \( 3 \times 3 \) Yukawa matrices \( y_f \) \( (f = u, d, e) \) can be calculated automatically in the \( \overline{\text{DR}} \) scheme at the scale \( M_Z \) from the known Standard Model fermion masses by setting \( y_f \) to the value automatic in the FlexibleSUSY model file. This is done for example in the CMSSM model file in Section 5. In this case FlexibleSUSY expresses the Yukawa couplings in terms of the fermion mass matrices \( m_u, m_d, m_e \). In the MSSM, for example, these relations read in the SLHA convention [64]

\[
y_u^{\overline{\text{DR}}}(M_Z) = \frac{\sqrt{2} m_u^T}{v_u},
\]

\[
y_d^{\overline{\text{DR}}}(M_Z) = \frac{\sqrt{2} m_d^T}{v_d},
\]

\[
y_e^{\overline{\text{DR}}}(M_Z) = \frac{\sqrt{2} m_e^T}{v_d},
\]

(22)

where the superscript \( T \) means transposition of a matrix. The fermion mass matrices are composed as

\[
m_u = \text{diag}(m_u^{\text{input}}, m_{e,\text{input}}, m_{l_{u,\text{susy}}}(M_Z)),
\]

(23)

\[
m_d = \text{diag}(m_d^{\text{input}}, m_{e,\text{input}}, m_{l_{d,\text{susy}}}(M_Z)),
\]

(24)

\[
m_e = \text{diag}(m_e^{\text{input}}, m_{\mu,\text{input}}, m_{l_{e,\text{susy}}}(M_Z)),
\]

(25)

where the values for \( m_{u,c,d,s,e,\mu}^{\text{input}} \) are read from the \text{SMINPUTS} block of the SLHA input file [63]. The CKM mixing matrix is currently set to unity and \( C\text{P}-\text{violating phases are set to zero. The third}
generation quark masses are calculated in the DR scheme from the SLHA user input quantities \( m_t^{\text{pole}}, m_b^{\text{MS}}(M_Z) \) and \( m_\tau^{\text{MS}}(M_Z) \) \cite{63}. In detail, the top quark DR mass is calculated as
\[
m_{t,\text{susy}}^{\text{DR}}(\mu) = m_t^{\text{pole}} + \text{Re} \Sigma^S_t(m_t^{\text{pole}})
+ m_t^{\text{pole}} \left[ \text{Re} \Sigma^L_t(m_t^{\text{pole}}) + \text{Re} \Sigma^R_t(m_t^{\text{pole}}) + \Delta m_t^{\text{(1),qcd}} + \Delta m_t^{\text{(2),qcd}} \right],
\]
where the \( \Sigma_t \) is the top one-loop self-energy without QCD contributions. The labels \( L, R, S \) denote the left-, right- and non-polarized part of the self-energy, \( \Sigma_t \). The separated QCD corrections \( \Delta m_t^{\text{(1),qcd}} \) and \( \Delta m_t^{\text{(2),qcd}} \) are taken from \cite{83,84} and read
\[
\Delta m_t^{\text{(1),qcd}} = -\frac{g_2^2}{12\pi^2} \left[ 5 - 3 \log \left( \frac{m_t^2}{\mu^2} \right) \right],
\]
\[
\Delta m_t^{\text{(2),qcd}} = \left( \Delta m_t^{\text{(1),qcd}} \right)^2
- \frac{g_3^2}{4608\pi^4} \left[ 396 \log^2 \left( \frac{m_t^2}{\mu^2} \right) - 1476 \log \left( \frac{m_t^2}{\mu^2} \right) - 48\zeta(3) + 2011 + 16\pi^2(1 + \log 4) \right].
\]
In Eqs. (27) and (28) \( m_t \) denotes the DR mass of the top quark. The DR mass of the bottom quark is calculated as \cite{83,85,63}
\[
m_{b,\text{susy}}^{\text{DR}}(\mu) = \frac{m_{b,\text{susy}}^{\text{DR}}(\mu)}{1 - \text{Re} \Sigma^\text{heavy}_b(m_{b,\text{susy}}^{\text{MS}})/m_b - \text{Re} \Sigma^L_b(m_{b,\text{susy}}^{\text{MS}}) - \text{Re} \Sigma^R_b(m_{b,\text{susy}}^{\text{MS}})},
\]
\[
m_{b,\text{SM}}^{\text{DR}}(\mu) = m_{b,\text{SM}}^{\text{MS}}(\mu) \left( 1 - \frac{\alpha_s}{3\pi} - \frac{23\alpha_s^2}{72\pi^2} + \frac{3g_2^2}{128\pi^2} + \frac{13g_3^2}{1152\pi^2} \right),
\]
where \( \tan \beta \) enhanced loop self-energy corrections are resummed. Finally, the DR mass of the \( \tau \) is calculated as
\[
m_{\tau,\text{susy}}^{\text{DR}}(\mu) = m_{\tau,\text{SM}}^{\text{DR}}(\mu) + \text{Re} \Sigma^\text{heavy}_\tau(m_{\tau,\text{SM}}^{\text{MS}})
+ m_{\tau,\text{SM}}^{\text{DR}}(\mu) \left[ \text{Re} \Sigma^L_\tau(m_{\tau,\text{SM}}^{\text{MS}}) + \text{Re} \Sigma^R_\tau(m_{\tau,\text{SM}}^{\text{MS}}) \right],
\]
\[
m_{\tau,\text{SM}}^{\text{DR}}(\mu) = m_{\tau,\text{SM}}^{\text{MS}}(\mu) \left( 1 - 3\frac{g_2^2 - g_3^2}{128\pi^2} \right).
\]
In the above equations \( \Sigma^\text{heavy}_{b,\tau} \) are the one-loop self-energies of the bottom and \( \tau \), where contributions from the gluon and photon are omitted. To convert the fermion masses from the \( \overline{\text{MS}} \) to the DR scheme the Yukawa coupling conversion from \cite{71} is used and it is assumed that the VEV is defined in the DR scheme.

6.2.3. Electroweak symmetry breaking

FlexibleSUSY assumes that each SUSY model contains Higgs bosons, which trigger a spontaneous breaking of the electroweak symmetry. The corresponding EWSB consistency conditions are formulated in FlexibleSUSY at the one-loop level as
\[
0 = \frac{\partial V^{\text{tree}}}{\partial v_i} - t_i, \quad (i = 1, \ldots, N)
\]
where $V^\text{tree}$ is the tree-level Higgs potential, $v_i$ is the VEV corresponding to the Higgs field $H_i$ and $t_i$ is the one-loop tadpole diagram of $H_i$. Already at the tree-level ($t_i = 0$) Eqs. (33) can have multiple solutions, depending on which parameters are chosen to be fixed by these equations. A well-known example is the real MSSM, where the $\mu$-parameter is chosen to be fixed by the EWSB equations. In this model, the EWSB equations, Eqs. (33) can only determine $|\mu|$, while the sign of $\mu$ is not fixed. This results in two solutions for $\mu$ of the form

$$
\mu = \text{sign } \mu \cdot |\mu|.
$$

(34)

Currently, FlexibleSUSY handles only real model parameters and renormalizable theories, which restricts the number of possible multiple solutions of Eqs. (33) to be less than or equal to $4N$. In some cases, as for example in the real MSSM, the different solutions are related by one or more global signs for the parameters, as for example in Eq. (34). FlexibleSUSY recognizes such cases and introduces these global signs as additional free parameters to allow the user to choose between the different solutions. The case of the real MSSM Eq. (34) is therefore handled automatically in FlexibleSUSY, because sign $\mu$ is automatically introduced as an additional free parameter.

If, however, the different solutions are not related by global signs, then FlexibleSUSY writes all solutions to the file `models/<model>/<model>_tree_level_EWSB_solution.m`. The user has then the option to pick a particular solution by setting it in the `TreeLevelEWSBSolution` variable in the model file. This is for example the case in the $Z_3$-violating NMSSM ($\text{SMSSM}$), which is shipped with FlexibleSUSY, where $\mu$ is chosen to be fixed by the EWSB equations: There the tree-level solution for $\mu$ has the form

$$
\mu = \frac{-v_s \lambda}{\sqrt{2}} + \text{sign } X \cdot \sqrt{\ldots}
$$

(35)

with sign $X$ as free parameter. When FlexibleSUSY solves the tree-level EWSB equations for $\mu$, $B\mu$ and $\xi_S$ it finds the two solutions and writes them to `models/SMSSM/SMSSM_tree_level_EWSB_solution.m` in the form

```plaintext
{{B[(Mu)] -> ...}},
{{(Mu) -> (-20*Sqrt[2]*vd*vS*(\[Lambda] + conj[\[Lambda]]) - Sqrt[\ldots])/(80*vd)},
 {\[Mu] -> (-20*Sqrt[2]*vd*vS*(\[Lambda] + conj[\[Lambda]]) + Sqrt[\ldots])/(80*vd)}
},
{{L[L1] -> ...}}
```

In the above solutions the dots stand for the full expression, which is left out here for better readability. Inspecting the two above solutions for $\mu$, one finds that both can be parametrized by an additional free sign in front of the $\text{Sqrt[\ldots]}$. The user can now introduce an additional free sign by hand in the `MINPAR` block

```plaintext
MINPAR = {
 {1, m0},
 {2, m12},
```
and set the the tree-level solution, parametrized in terms of \( \text{Sign}[X] \), in the `TreeLevelEWSBSolution` variable in the model file:

```plaintext
TreeLevelEWSBSolution = {
    { B[\[Mu]], ... },
    { \[Mu], (-20*Sqrt[2]*vd*vS*(\[Lambda] + conj[\[Lambda]])
         + Sign[X] * Sqrt[...])/(80*vd) },
    { L[L1], ... }
};
```

One can now choose between the two solutions by setting entry 4 in the `MINPAR` block of the SLHA input file to either +1 or −1. See `model_files/SMSSM/FlexibleSUSY.m.in` for a complete example model file. If the user decides to not pick a particular solution by leaving the variable `TreeLevelEWSBSolution` empty, FlexibleSUSY tries to find a solution to the tree-level EWSB equations numerically via iteration. In this case, however, the user does not have the option to choose between the different solutions.

If a solution of the tree-level EWSB equations has been found, the one-loop equations (\ref{eq:one_loop_tadpoles}) are solved simultaneously using the iterative multi-dimensional root finder algorithm `gsl_multiroot_fsolver_hybrid` from the GNU Scientific Library (GSL). If no root can be found, the `gsl_multiroot_fsolver_hybrids` algorithm is tried as alternative, which uses a variable step size but might be a little slower.

In the CMSSM example from Section 5 the Eqs. \ref{eq:one_loop_tadpoles} are expressed in the form of the following C++ function:

```plaintext
int MSSM<Two_scale>::tadpole_equations(const gsl_vector* x, void* params,
    gsl_vector* f)
{
    ... double tadpole[number_of_ewsb_equations];

    model->set_BMu(gsl_vector_get(x, 0));
    model->set_Mu(INPUT(SignMu) * Abs(gsl_vector_get(x, 1)));

    // calculate tree-level tadpole eqs.
    tadpole[0] = model->get_ewsb_eq_vd();
    tadpole[1] = model->get_ewsb_eq_vu();

    // subtract one-loop tadpoles
    if (ewsb_loop_order > 0) {
        model->calculate_DRbar_masses();
        tadpole[0] -= Re(model->tadpole_hh(0));
        tadpole[1] -= Re(model->tadpole_hh(1));
    }

    for (std::size_t i = 0; i < number_of_ewsb_equations; ++i)
        gsl_vector_set(f, i, tadpole[i]);
}
```
The function parameter x is the vector of EWSB output parameters (defined in EWSBOutputParameters) and f is a vector which contains the one-loop EWSB Eqs. (33). This tadpole_equations() function is passed to the root finder, which searches for values of the model parameters µ and Bµ until the Eqs. (33) are fulfilled.

If higher accuracy is required additional routines with higher order corrections can be added by setting UseHiggs2LoopMSSM = True in the model file. For example in the MSSM by default FlexibleSUSY adds two-loop Higgs FORTRAN routines supplied by P. Slavich from [51, 53] to add two-loop corrections of \(O(\alpha_t \alpha_s)\), \(O(\alpha_b \alpha_s)\), \(O(\alpha_t^2)\), \(O(\alpha_b^2)\), and \(O(\alpha_t \alpha_b)\). In the NMSSM the same contributions can be added by setting UseHiggs2LoopNMSSM = True in the model file.

6.3. Tree-level spectrum

The tree-level \(\overline{\text{DR}}\) masses are calculated from the \(\overline{\text{DR}}\) model parameters by diagonalizing the mass matrices returned from SARAH\('\text{MassMatrix}()\). The numerical singular value decomposition is performed by the Eigen library routine \(\text{Eigen::JacobiSVD}\) for matrices with less than four rows and columns, and the LAPACK routines zgsvd, dgsvd for larger matrices. For the other types of diagonalization, \(\text{Eigen::SelfAdjointEigenSolver}\) from Eigen is used regardless of the matrix size. Note, that FlexibleSUSY uses double precision floating point data types with 15 significant digits to store the mass matrices and the mass eigenvalues. In case a particle multiplet contains a very split mass hierarchy, where the mass difference between the smallest and the largest mass in the multiplet is of the order or greater than 10 orders of magnitude, double precision data types are no longer sufficient. In this case we recommend to either split the multiplet into sub-multiplets with smaller mass hierarchies, or integrate out the heavy states.

FlexibleSUSY uses the following conventions for the diagonalization: A mass matrix \(M^2\) for real scalar fields \(\phi_i\) is diagonalized with an orthogonal matrix \(O\) as

\[
L_{m,\text{real scalar}} = -\frac{1}{2} \phi^T M^2 \phi = -\frac{1}{2} (\phi^m)^T M_D^2 \phi^m, \\
M^2 = (M^2)^T, \quad \phi^m = O \phi, \quad M_D^2 = O M^2 O^T, \quad O^T O = 1, 
\]

where \(M_D^2\) is diagonal and \(\phi_i^m\) are the mass eigenstates. In case of complex scalar fields \(\phi_i\) we use

\[
L_{m,\text{complex scalar}} = -\phi^\dagger M^2 \phi = - (\phi^m)^\dagger M_D^2 \phi^m, \\
M^2 = (M^2)^\dagger, \quad \phi^m = U \phi, \quad M_D^2 = U M^2 U^\dagger, \quad U^\dagger U = 1.
\]

A (possibly complex) symmetric mass matrix \(Y\) for Weyl spinors \(\psi_i\) is diagonalized as

\[
L_{m,\text{fermion}}^{\text{symm.}} = -\frac{1}{2} \psi^T Y \psi + \text{h.c.} = -\frac{1}{2} \chi^T Y_D \chi + \text{h.c.}, \\
Y = Y^T, \quad Y_D = Z^* Y Z^\dagger, \quad \chi = Z \psi, \quad Z^\dagger Z = 1.
\]

where \(Y_D\) is diagonal and \(\chi_i\) are the mass eigenstates. The phases of \(Z\) are chosen such that all mass eigenvalues are positive. In case of a non-symmetric mass matrix \(X\) for Weyl spinors \(\psi_i\) we
L_{m,\text{fermion}}^{\text{svd}} = -(\psi^\dagger)^T X \psi^+ + \text{h.c.} = -(\chi^\dagger)^T X_D \chi^+ + \text{h.c.}, \quad (42)
\chi^+ = V \psi^+, \quad \chi^- = U \psi^-, \quad X_D = U^* X V - 1, \quad U^\dagger U = 1 = V^\dagger V, \quad (43)

where we are again choosing the phases of $U$ and $V$ such that all mass eigenvalues are positive.

6.4. Two-scale fixed point iteration

As explained at the beginning of Section 6, the RGEs plus the user-defined boundary conditions on the model parameters form a boundary value problem. FlexibleSUSY provides a default two-scale boundary value problem solver, which tries to find a set of model parameters consistent with all constraints at all scales. It does so by running iteratively between the scales of all boundary conditions, imposing the constraints (by calling the corresponding apply() function) and checking for convergence after each iteration. This approach is described in [86] originally for the MSSM and is widely implemented in SUSY spectrum generators. Despite sharing the same algorithm with others, the boundary value problem solver class from FlexibleSUSY, named RGFlow, has two notable properties. First, it extends the aforementioned procedure to towers of models. If the problem involves more than one model, RGFlow matches one model to the next after running the model parameters to the matching scale. Second, RGFlow is an abstract implementation of the algorithm, unaware of physics, in that it is free of hard-wired model-dependent code related to RGEs, boundary or matching conditions, or initial guesses. All these pieces of physics information are carried by separate objects which one then links to RGFlow to set up a boundary value problem. This modular design makes it easy to replace any of the above components, as shall be demonstrated in Section Appendix A.2.

In more detail the two-scale algorithm used in FlexibleSUSY, as applied to a problem with a single MSSM-like model, works as follows, see also Figure 2:

**Initial guess:** The RG solver starts to guess all model parameters at the low-scale.
1. At the $M_Z$ scale the gauge couplings $g_{1,2,3}$ are set to the known Standard Model values (ignoring threshold corrections).
2. The user-defined initial guess at the low-scale (defined in InitialGuessAtLowScale) is imposed. In the example given in Section 5 the Higgs VEVs are set to $v_d = v \cos \beta$, $v_u = v \sin \beta$, \quad (44)
where $v = 246.22$ GeV. Afterwards, the Yukawa couplings $y_{u,d,e}$ of the SUSY model are set from the known Standard Model Yukawa couplings using the tree-level relations (ignoring SUSY radiative corrections).
3. The SUSY parameters are run to the user-supplied first guess of the high-scale (HighScaleFirstGuess).
4. The high-scale boundary condition is imposed (defined in HighScaleInput). Afterwards, the user-defined initial guess for the remaining model parameters (defined in InitialGuessAtHighScale) is imposed. In the example given in Section 5 the superpotential parameter $\mu$ is set to the value 1.0 and its corresponding soft-breaking parameter $B\mu$ is set to zero.
5. All model parameters are run to the first guess of the low-scale (LowScaleFirstGuess).
6. The EWSB eqs. are solved at the tree-level.
7. The DR mass spectrum is calculated.

At this point all model parameters are set to some initial values and a first estimation of the DR mass spectrum is known. Now the actual iteration starts.
Fixed-point iteration:

1. All model parameters are run to the low-scale (\texttt{LowScale}).
   (a) The DR mass spectrum is calculated.
   (b) The low-scale is recalculated. In the above example this step is trivial, because the 
       low-scale is fixed to be \( M_Z \).
   (c) The DR gauge couplings \( g_{1,2,3}(M_Z) \) of the SUSY model are calculated using 
       threshold corrections as described in Section 6.2.1.
   (d) The user-defined low-scale constraint is imposed (\texttt{LowScaleInput}). In the example 
       above, the Yukawa couplings are calculated automatically as described in Section 6.2.2 
       and the Higgs VEVs are set to
       \[
       v_u(M_Z) = 2 M^\text{DR}_Z(M_Z) \sqrt{0.6 g_1^2(M_Z) + g_2^2(M_Z) \sin \beta(M_Z)}.
       \]
       Since the Hypercharge gauge coupling \( g_1 \) is GUT normalized, the normalization factor 
       \( \sqrt{3/5} \) has to be included in the above relations.

2. Run all model parameters to the high-scale (\texttt{HighScale}).
   (a) Recalculate the high-scale as
       \[
       M'_X = M_X \exp \left( \frac{g_2(M_X) - g_1(M_X)}{\beta_{g_1} - \beta_{g_2}} \right),
       \]
       where \( \beta_{g_i} \) is the two-loop \( \beta \)-function of the gauge coupling \( g_i \). The value \( M'_X \) is used as 
       new high-scale in the next iteration.
   (b) Impose the high-scale constraint (\texttt{HighScaleInput}). In the CMSSM example the following 
       soft-breaking parameters are fixed to the universal values \( m_0, M_{1/2} \) and \( A_0 \):
       \[
       A^f(M_X) = A_0 \quad \text{for } f = u, d, e, \]
       \[
       m^2_{H_i}(M_X) = m^2_0 \quad \text{for } i = 1, 2, \]
       \[
       m^2_f(M_X) = m^2_{01} \quad \text{for } f = q, l, d, u, e, \]
       \[
       M_i(M_X) = M_{1/2} \quad \text{for } i = 1, 2, 3.
       \]

3. Run model parameters to the SUSY-scale (\texttt{SUSYScale}).
   (a) Calculate the DR mass spectrum.
   (b) Recalculate the SUSY-scale \( M_S \) as
       \[
       M_S = \sqrt{\prod_{i=1}^{6} m_{\tilde{g}_i}^2 + |(Z_u)_{ij}|^2 + |(Z_d)_{ij}|^2},
       \]
       where \( m_{\tilde{g}_i} \) is the DR mass of the \( i \)th up-type squark.
   (c) Impose the SUSY-scale constraint (\texttt{SUSYScaleInput}). In the example above, this step is 
       trivial since \texttt{SUSYScaleInput} is set to be empty.
(d) Solve the EWSB equations iteratively at the loop level. In the MSSM example from above leading two-loop corrections have been enabled by setting `UseHiggs2LoopMSSM = True`. This will add two-loop tadpole contributions to the effective Higgs potential during the EWSB iteration.

4. If not converged yet, goto 1. Otherwise, finish the iteration.

If the fixed-point iteration has converged, all DR model parameters are known at all scales between \texttt{LowScale} and \texttt{HighScale}. In this case all model parameters are run to the SUSY-scale and the pole-mass spectrum is calculated as described in Section 6.5. If the user has chosen a specific output scale for the running DR model parameters by setting entry 12 in block \texttt{MODSEL} in the SLHA input file, all model parameters are finally run to the defined output scale.

During the fixed-point iteration several problems can appear. First of all, the iteration is not guaranteed to converge. If the desired accuracy goal is not achieved with the given maximum number of iterations, FlexibleSUSY will set the \texttt{no\_convergence} flag in the \texttt{Problems} class. This class monitors the problem status of the spectrum generator during the iteration and can be obtained from the model class via the \texttt{get\_problems()} function. Besides non-convergence, solving the EWSB conditions (33) numerically with the desired accuracy might fail. In this case the \texttt{no\_ewsb} flag is set. Furthermore, in intermediate iteration steps tachyonic states might appear, which are ignored but nevertheless monitored in the \texttt{Problems} class. If tachyons still exist after the iteration has converged the mass spectrum is marked as invalid by setting entry 4 in the \texttt{SPINFO} block in the SLHA output file. Finally, during the RG running some couplings might become non-perturbative. In this case the iteration stops setting the \texttt{no\_perturbative} flag.
It is important to note that in the case of such problem points it is non-trivial to judge whether this is because there is no physical solution for the given parameter space point or a solution exists but the fixed point iteration is unable to find the solution. While FlexibleSUSY makes it as easy as possible to find spectra, when studying new models a physical understanding of the model is still essential and this can help the user determine why such problems arise.

Nonetheless FlexibleSUSY provides help for such cases in several ways. One may adjust initial guesses specified in the FlexibleSUSY model file, such as changing the choice of HighScaleFirstGuess or altering HighScaleMinimum and HighScaleMaximum which can be used to push the iteration back towards where the solution should be if it gets off track. For experienced users the clear code structure also allows the possibility of direct adaption of the code.

Finally instead of tinkering with the two-scale solver one may wish to replace it entirely. The modular design of FlexibleSUSY allows for the solver for the boundary value problem to be replaced. An alternative solver with potentially better convergence properties (at the expense of slower speed) is already planned for a later release.

6.5. Pole masses

After the solver routine has finished and convergence has been achieved, all DR parameters consistent with the EWSB conditions, low energy data and all user-supplied boundary conditions are known at any scale between LowScale and HighScale.

The (physical) pole mass spectrum can now be calculated. FlexibleSUSY uses the full one-loop self-energies and tree-level mass matrices obtained from SARAH to calculate the pole masses, which means finding the values $p$ that solve the equation

$$0 = \det \left[ p^2 \mathbf{1} - m_{f,1L}(p^2) \right]. \quad (53)$$

Here the one-loop mass matrix $m_{f,1L}(p^2)$ for field $f$ is given in terms of the tree-level mass matrix $m_f$ and the self-energy $\Sigma_f(p^2)$ as

- **Scalars** $\phi$:
  $$m_{\phi,1L}(p^2) = m_\phi - \Sigma_\phi(p^2), \quad (54)$$

- **Majorana fermions** $\chi$:
  $$m_{\chi,1L}(p^2) = m_\chi - \frac{1}{2} \left[ \Sigma^S_\chi(p^2) + \Sigma^T_\chi(p^2) + \left( \Sigma^L_{\chi,\chi}(p^2) + \Sigma^R_{\chi,\chi}(p^2) \right) \right] m_\chi$$
  $$+ m_\chi \left( \Sigma^L_\chi(p^2) + \Sigma^R_\chi(p^2) \right), \quad (55)$$

- **Dirac fermions** $\psi$:
  $$m_{\psi,1L}(p^2) = m_\psi - \Sigma^S_\psi(p^2) - \Sigma^R_\psi(p^2) - \Sigma^L_\psi(p^2) - \Sigma^R_\psi(p^2), \quad (56)$$

Eq. (53) can be solved by diagonalizing the one-loop mass matrix $m_{f,1L}(p^2)$. However, since $m_{f,1L}(p^2)$ depends on the momentum $p$, an iteration over $p$ must be performed. Since this iteration can be very time consuming for large field multiplets, FlexibleSUSY provides two approximative procedures with a shorter run-time in addition to the iterative procedure. In the FlexibleSUSY model file the two approximative procedures are called LowPrecision and MediumPrecision. The iterative procedure is called HighPrecision. The procedure to be used can be set in the model file for each field. The default setting is

<table>
<thead>
<tr>
<th>DefaultPoleMassPrecision</th>
<th>MediumPrecision;</th>
</tr>
</thead>
<tbody>
<tr>
<td>HighPoleMassPrecision</td>
<td>{hh, Ah, Hpm};</td>
</tr>
<tr>
<td>MediumPoleMassPrecision</td>
<td>{};</td>
</tr>
<tr>
<td>LowPoleMassPrecision</td>
<td>{};</td>
</tr>
</tbody>
</table>
In the variable `DefaultPoleMassPrecision` the default pole mass calculation precision to be used for all particles is selected. Possible values are `LowPrecision`, `MediumPrecision` and `HighPrecision`. The values `LowPrecision` and `MediumPrecision` correspond to the two approximations described below and `HighPrecision` corresponds to the iterative determination of the pole masses. In the variables `HighPoleMassPrecision`, `MediumPoleMassPrecision` and `LowPoleMassPrecision` the pole mass calculation precision can be changed for individual particles. The settings in these variables overwrite the setting in `DefaultPoleMassPrecision` for these particles. In the above example the pole masses of all particles are calculated with `MediumPrecision`, except for the Higgs boson pole masses, which are calculated with the iterative procedure (`HighPrecision`).

The three different pole mass calculation procedures work as follows:

- **LowPrecision**: This option provides the lowest precision but is also the fastest one. Here the one-loop mass matrix \( m_{f,1L}^{\text{low}} \) is calculated exactly once as

\[
\forall i,j : (m_{f,1L}^{\text{low}})_{ij} = (m_{f,1L}(p^2 = m_f m_j))_{ij},
\]

where \( m_f \) is the \( i \)th mass eigenvalue of the tree-level mass matrix \( m_f \). Afterwards, \( m_{f,1L}^{\text{low}} \) is diagonalized and the eigenvalues are interpreted as pole masses \( m_{f,i}^{\text{pole}} \). This method neglects terms of the form

\[
\left[ (m_{f,k}^{\text{pole}})^2 - m_{f,k}^2 \right] \frac{\partial m_{f,1L}(p^2)}{\partial p^2} \bigg|_{p^2 = m_f m_j},
\]

which are formally of two-loop order. The method is imprecise if the self-energy corrections to the mass matrix are large or the tree-level mass spectrum of the multiplet is very split. Note: We strongly discourage the use of this method for the determination of the Higgs pole masses, as the result will be very imprecise due to the large loop corrections. FlexibleSUSY will print a warning if this method is used for any Higgs boson.

- **MediumPrecision** (default): This option provides calculation with medium precision with a medium execution time. Here the one-loop mass matrix \( m_{f,1L}^{\text{medium}} \) is calculated \( n \) times as

\[
(m_{f,1L}^{\text{medium}})_{ij}^{(k)} = (m_{f,1L}(p^2 = m_f^2))_{ij}, \quad k = 1, \ldots, n,
\]

where \( m_{f,k} \) is the \( k \)th mass eigenvalue of the tree-level mass matrix \( m_f \). Afterwards, each mass matrix \( m_{f,1L}^{\text{medium}}(k) \) is diagonalized and the \( k \)th eigenvalue is interpreted as pole mass \( m_{f,k}^{\text{pole}} \). Thereby for the \( k \)th eigenvalue two-loop terms of the form

\[
\left[ (m_{f,k}^{\text{pole}})^2 - m_{f,k}^2 \right] \frac{\partial m_{f,1L}(p^2)}{\partial p^2} \bigg|_{p^2 = m_{f,k}^2},
\]

are neglected. This method is imprecise if the self-energy corrections to the mass matrix are large. Note, that this method is used in Softsusy to calculate the pole masses of the non-Higgs fields.

- **HighPrecision**: This option solves Eq. (53) exactly by iterating over the momentum \( p \). It therefore provides the determination of the pole masses with highest precision, but has also
the highest execution time. Here the one-loop mass matrix $m^\text{high}_{j,k}$ is diagonalized $n$ times, as in the case of MediumPrecision, resulting in $n$ pole masses $m^\text{pole}_{f_k}$ ($k = 1, \ldots, n$). Afterwards, the diagonalization is repeated, this time using the calculated pole masses $m^\text{pole}_{f_k}$ for the momentum calculation $p^2 = (m^\text{pole}_{f_k})^2$. The iteration stops if convergence is reached.

A numerical comparison of the three different methods for a specific CMSSM parameter point can be found in Table 1. One finds that (i) the calculated lightest $CP$-even Higgs pole mass, $m_h$, differs about 1.2 GeV between MediumPrecision and HighPrecision, due to large loop corrections. Since the experimental Higgs mass uncertainty is currently around 0.4 GeV [61], we strongly recommend the use of HighPrecision to calculate the Higgs pole mass (this is the default). Especially, if two-loop contributions to the Higgs tadpoles and self-energies are added MediumPrecision must not be used, because it neglects terms of two-loop order. The Higgs boson mass for the LowPrecision method is not given in the table, as it will lead to an imprecise result and is therefore strongly discouraged to be used, see Section 6.5. (ii) The gluino pole mass, $m_\tilde g$, is given in the second row. Since the gluino does not mix with other particles, there is no difference between LowPrecision and MediumPrecision. Not neglecting the two-loop terms by using HighPrecision increases the gluino mass about 0.5% for this parameter point. (iii) The pole masses of the lightest and heaviest neutralinos, $m_\tilde \chi^0_1$ and $m_\tilde \chi^0_2$, are given in the rows 3–4. Since the momentum-dependent loop-corrections to the lightest neutralino mass are small for this parameter point, its pole mass varies only in the sub-GeV range between the three methods. However, the run-time of the LowPrecision method is more than a factor 10 smaller than of the HighPrecision, due to the complicated structure of the loop corrections in Eq. (55). (iv) The pole masses of the lightest sfermions are given in rows 5–7. Since these particles are contained in 6-plets, the run-time for the calculation of their pole masses is dramatically increased by around a factor 20 between LowPrecision and HighPrecision. However, since the change in the lightest sfermion masses between the three different methods is less than 0.3%, one can consider calculating them with MediumPrecision only.

Table 1: Comparison of pole masses with different calculation methods for the CMSSM with $m_0 = M_1/2 = 1$ TeV, $A_0 = -3.3$ TeV, $\tan \beta = 10$, $\text{sign} \mu = +1$. In brackets the time used to calculate the pole masses of the whole multiplet is given.

For the Higgs states two-loop corrections to the self-energies can optionally be added by setting UseHiggs2LoopMSSM = True in the MSSM or UseHiggs2LoopNMSSM = True in the NMSSM in the model file. The former provides routines that call the two-loop Higgs FORTRAN routines supplied by P. Slavich from [48, 50, 51, 52, 53] for calculating corrections of $O(\alpha_1 \alpha_2), O(\alpha_2 \alpha_2), O(\alpha_2^2), O(\alpha_2^3)$, $O(\alpha_2^4)$ and $O(\alpha_1 \alpha_3)$. The latter adds corrections calculated in the NMSSM at $O(\alpha_1 \alpha_2), O(\alpha_2 \alpha_3)$ from [61] and partial corrections for the order $O(\alpha_2^2), O(\alpha_2^2), O(\alpha_2^2)$ and $O(\alpha_1 \alpha_4)$ from the MSSM.

32
These corrections can then be included in the calculation of the Higgs pole masses when running the spectrum generator by setting the appropriate SLHA flags.

When two-loop corrections have been enabled in the SLHA file by setting entry 4 of the FlexibleSUSY block to 2 the user may also select individual corrections. The FlexibleSUSY block entries 9, 10, 11 and 12, correspond to two-loop corrections of the order $O(\alpha_t \alpha_s)$, $O(\alpha_b \alpha_s)$, $O((\alpha_t + \alpha_b)^2)$ and $O(\alpha_t^2)$ respectively and will be disabled when the corresponding entry is set to zero. In this way, for example, in the NMSSM the user may decide not to use the partial corrections at order $O((\alpha_t + \alpha_b)^2)$ and $O(\alpha_t^2)$, all of which have only been computed in the MSSM.

Since the Higgs mass is a very important measurement and the two-loop corrections can be larger than the current experimental error [61] we recommend to set these switches to True in any MSSM and NMSSM-like model. However in such models the user should still consider whether these corrections are really the leading corrections in the model or there are other potentially large two-loop corrections which are missing. For models with a more extended Higgs sector we recommend that the leading log two-loop corrections are estimated by generalizing those of the MSSM or NMSSM.

7. Flexible Applications

By definition, research is an endeavor to find something new. Therefore, it can often be the case that a spectrum generator right out of the box is not enough. FlexibleSUSY attempts to offer a clean interface through which one can exploit its facilities while undergoing a minimal amount of frustration, when one programs for a wide variety of studies. We provide two basic levels for the user to create a custom spectrum generator: (i) The Mathematica level, where one writes or adapts a model file and (ii) the C++ level, where the generated classes can be extended, recombined or replaced by self-made modules. In what follows, adaptions on these two levels shall be demonstrated by presenting a few use cases at differing degrees of complexity.

To avoid confusion, it should be mentioned that the code snippets presented below are not verbatim listings of the files included in the package. They have been tailored retaining the semantics for conciseness.

7.1. Adapting model files

There are simple but interesting goals that one can achieve only by working on Mathematica files. The outcome thus obtained from FlexibleSUSY might already include a fully-fledged program that is useful in physics analysis. In a more advanced project, one might utilize the produced libraries as building blocks that constitute the target application. For a general account of the FlexibleSUSY model files, refer to Section 5.

---

3 In FlexibleSUSY a model is MSSM-like if (i) its superpotential is approximately given by the MSSM one, (ii) it implements $R$-parity conservation or something equivalent, and (iii) contains two $CP$-even and $CP$-odd Higgs bosons, where one $CP$-odd Higgs boson may be a Goldstone boson, all with an MSSM-like coupling to $t$, $b$ and $\tau$.

4 In FlexibleSUSY a model is NMSSM-like if (i) its superpotential is approximately given by the NMSSM one, (ii) it implements $R$-parity conservation or something equivalent, and (iii) contains three $CP$-even and $CP$-odd Higgs bosons, where one or two $CP$-odd Higgs bosons may be Goldstone bosons, all with an NMSSM-like coupling to $t$, $b$ and $\tau$. Examples for NMSSM-like models are the USSM and the $E_6$SSM.
7.1.1. Changing boundary conditions

As already emphasized in Section 3, the modular design of FlexibleSUSY makes it straightforward to replace a boundary condition object. The question then becomes how one could obtain an alternative boundary condition class, apart from writing one by hand. The meta code feature of FlexibleSUSY offers great assistance in this respect. An example shall be presented to illustrate how this works.

In the literature, there is a popular alternative to the CMSSM boundary condition under which the Higgs soft masses are allowed to be different from the universal mass of the other scalars \[87\]. One might implement this non-universal Higgs-mass MSSM (NUHMSSM) scenario simply by modifying the model description given to FlexibleSUSY. A section of the FlexibleSUSY.m.in file is listed below:

```
EXTPAR = {{1, mHd2In}, {2, mHu2In}};
HighScaleInput = {
{mHd2, mHd2In}, {mHu2, mHu2In},
{T[Ye], Azero*Ye}, {T[Yd], Azero*Yd}, {T[Yu], Azero*Yu},
{mu2, UNITMATRIX[3] m0^2}, {me2, UNITMATRIX[3] m0^2},
{MassB, m12}, {MassWB, m12}, {MassG, m12}
};
```

Since \( m_{Hd2} \) and \( m_{Hu2} \) are to be fixed at constants different from \( m_0 \), two additional input parameters, \( m_{Hd2In} \) and \( m_{Hu2In} \), holding those constants, are introduced in the list \( \text{EXTPAR} \). These input parameters are then declared to be the high-scale values of \( m_{Hd2} \) and \( m_{Hu2} \) in line 4. The rest of the boundary conditions is the same as in the CMSSM. In the SLHA input file, the parameter indices 1 and 2 of \( m_{Hd2In} \) and \( m_{Hu2In} \), declared in \( \text{EXTPAR} \) above, must appear as the first field in each line in the \( \text{EXTPAR} \) block:

```
Block EXTPAR
  1 10000 # mHd2In
  2 -2500 # mHu2In
```

Note that the two additional input parameters are chosen to have mass dimension 2, unlike \( m_0 \). This makes it easy to try both signs of the high-scale value of either soft Higgs mass squared, as exemplified in line 3. If one were not interested in a negative boundary value of \( m_{Hu2} \) for instance, then a dimension-1 parameter might instead be introduced whose square is equated with \( m_{Hu2} \).

The full implementation is available in \texttt{model_files/NUHMSSM/}. To try it out, do the following:

```
$ ./createmodel --name=NUHMSSM --sarah-model=MSSM
$ ./configure --with-models=NUHMSSM
$ make
$ models/NUHMSSM/run_NUHMSSM.x
   --slha-input-file=models/NUHMSSM/LesHouches.in.NUHMSSM
```

Notice the \(--\text{sarah-model}=\text{MSSM}\) flag in line 1. It tells the \texttt{createmodel} script to reuse the MSSM specification in SARAH to generate the C++ program. Another remark is in order regarding the naming convention of specimen SLHA input files. The \texttt{createmodel} script assumes that their names
are in the form LesHouches.in* (case-insensitive). If the script finds such files in model_files/<model>/, it installs them into the model directory. The argument to --slha-input-file= in line 4 has been thus created.

7.1.2. Extending existing models

The preceding example was a modest alteration of a physics scenario in that an existing model has been reused. A more non-trivial modification might involve an extension of the particle content as well as the interactions. One of the simplest classes of models beyond the MSSM is those with additional gauge-singlet fields. In what follows, a supersymmetric type-I see-saw scenario \[88\] shall be considered. For this, two extensions of the MSSM are introduced: MSSMRHN with three extra neutral (heavy) chiral superfields, and MSSMD5O with the dimension-5 neutrino mass operator added to the superpotential. Both models are included in the package.

The name MSSMRHN of the first model stands for the MSSM plus right-handed neutrinos. One needs to prepare an input file to SARAH which might be placed in <FlexibleSUSY-root>/sarah/MSSMRHN/ or <SARAH-root>/Models/MSSMRHN/. The input file MSSMRHN.m contains the declaration of the three-generation singlets:

```
SuperFields[[8]] = {v, 3, conj[vR], 0, 1, 1, RpM};
```

as well as the neutrino Yukawa couplings and the Majorana mass terms of the singlets:

```
```

Further declarations inform SARAH of how to form Dirac spinors out of the new Weyl spinors and how the scalars and the fermions mix to comprise the mass eigenstates:

```
DEFINITION[GaugeES][DiracSpinors] = {
  Fu1 -> {FuL, 0}, Fu2 -> {0, FuR},
  Fv1 -> {FvL, 0}, Fv2 -> {0, FvR},
  ... ,
};

DEFINITION[EWSB][MatterSector] = {
  {{SuL, SuR}, {Su, ZU}},
  {{SvL, SvR}, {Sv, ZV}},
  ... ,
  {{fB, fW0, Fhd0, Fhu0}, {L0, ZN}},
  {{FvL, conj[FvR]}, {FV, UV}},
  {{fWm, Fhdm}, {fWp, Fhop}}, {{Lm, UM}, {Lp, UP}}},
  {{FuL, conj[FuR]}}, {{FUL, ZUL}, {FUR, ZUR}}
};

DEFINITION[EWSB][DiracSpinors] = {
  Fu -> {FUL, conj[FUR]},
  Fv -> {FV, conj[FV]},
  Chi -> {L0, conj[L0]},
  Cha -> {Lm, conj[Lp]},
  ... ,
};
```
With respect to the MSSM file, the newly added lines are 6, 12, 15, and 22. Notice that the (left- and right-handed) neutrino mixing in line 15 resembles the neutralino mixing in line 14. Due to the Majorana mass term in the superpotential, the six neutrino mass eigenstates are described in terms of Majorana spinors like the neutralinos.

One should then add descriptions of the new states in the file `particles.m`:

```plaintext
ParticleDefinitions[\text{GaugeES}] = {
    \{Fv1, \{\text{Description} \rightarrow \text{"Dirac Left Neutrino"}\}\},
    \{Fv2, \{\text{Description} \rightarrow \text{"Dirac Right Neutrino"}\}\},
    \{SvR, \{\text{Description} \rightarrow \text{"Right Sneutrino"}, \LaTeX \rightarrow \"\tilde{\nu}_R\"\}\},
    ...
};
ParticleDefinitions[\text{EWSB}] = {
    \{Sv, \{\text{Description} \rightarrow \text{"Sneutrinos"}, \text{PDG} \rightarrow \{1000012, 1000014, 1000016, 2000012, 2000014, 2000016\}\}\},
    \{Fv, \{\text{Description} \rightarrow \text{"Neutrinos"}, \text{PDG} \rightarrow \{12, 14, 16, 9900012, 9900014, 9900016\}\}\},
    ...
};
```

In line 12, one finds PDG codes beginning with 99. Such numbers are available for a program author’s private use \[81\]. The new parameters in the superpotential and the soft supersymmetry breaking sector are to be described in `parameters.m`:

```plaintext
ParameterDefinitions = {
    \{UV, \{\text{Description} \rightarrow \text{"Neutrino - Mixing - Matrix"}\}\},
    \{Yv, \{\text{Description} \rightarrow \text{"Neutrino - Yukawa - Coupling"}\}\},
    \{T[Yv], \{\text{Description} \rightarrow \text{"Trilinear - Neutrino - Coupling"}\}\},
    \{Mv, \{\LaTeX \rightarrow \"M_v\", \text{OutputName} \rightarrow \text{Mv}, \text{LesHouches} \rightarrow \text{Mv}\}\},
    \{B[Mv], \{\LaTeX \rightarrow \"B_v\", \text{OutputName} \rightarrow \text{BMv}, \text{LesHouches} \rightarrow \text{BMv}\}\},
    \{mv2, \{\text{Description} \rightarrow \text{"Softbreaking right Sneutrino Mass"}\}\},
    ...
};
```

For further details on how to write model files for SARAH, we refer to its manual \[67, 48\].

Finally, it remains to put `FlexibleSUSY.m` in `model_files/MSSMRHN/`. The high-scale boundary conditions therein might read:

```plaintext
HighScaleInput = {
    \{mv2, \text{UNITMATRICE}[3, \text{m0-2}]\},
    \{T[Yv], \text{Azero}\ast Yv\},
    \{B[Mv], \text{LHInput}[B[Mv]]\},
    ...
};
```

36
The second model is called MSSMD5O, standing for the MSSM including the dimension-5 operator. Obviously, one can compose it by adding the additional term to the superpotential in `MSSMD5O.m`:

```latex
+ WOp/2 l.Hu.l.Hu;
```

where line 2 contains the dimension-5 operator multiplied by its coefficient matrix \( WOp \). The declarations of the neutrino Dirac spinors and mixing are very similar to those in the MSSMRHN, except that \( FvR \) is absent.

One can specify the low-scale constraints on \( WOp \) in `model_files/MSSMRHN/FlexibleSUSY.m.in`:

```latex
EXTPAR = {
  {1, mv1}, {2, mv2}, {3, mv3},
  {4, ThetaV12}, {5, ThetaV13}, {6, ThetaV23},
  {7, YvDiag1}, {8, YvDiag2}, {9, YvDiag3}
};

UPMNS = Module[{s12 = Sin @ ThetaV12, c12 = Cos @ ThetaV12, s13 = Sin @ ThetaV13, c13 = Cos @ ThetaV13, s23 = Sin @ ThetaV23, c23 = Cos @ ThetaV23},
  {{ c12 c13 , s12 c13 , s13 },
   {-s12 c23 - c12 s23 s13 , c12 c23 - s12 s23 s13 , s23 c13 },
   { s12 s23 - c12 c23 s13 , -c12 s23 - s12 c23 s13 , c23 c13 }}];

mv = conj[UPMNS].DiagonalMatrix[{mv1, mv2, mv3}].Transpose[conj @ UPMNS];

LowScaleInput = Join[
  { (* MSSM low-scale constraints *) },
  Flatten[Table[{WOp[i,j], mv[[i,j]] / (vu/Sqrt[2])^-2}, {i,3}, {j,3}], 1]
];

InitialGuessAtLowScale = Join[
  { (* MSSM initial guesses at low scale *) },
  Flatten[Table[{WOp[i,j], mv[[i,j]] / (vu/Sqrt[2])^-2}, {i,3}, {j,3}], 1]
];
```

The `EXTPAR` list contains the input parameters to be read from the corresponding SLHA block. The low-energy neutrino mass eigenvalues and mixing angles are declared in lines 2–3. They are followed by the neutrino Yukawa eigenvalues, which shall be used as part of the matching condition described in Appendix A.1. The constraint on and the initial guess of \( WOp \) in lines 21 and 26 should be self-explanatory.

With the above set of input files, FlexibleSUSY can generate the C++ class libraries, `libMSSMRHN` and `libMSSMD5O`. These products shall be employed as the two effective theories in the implementation of the see-saw mechanism. To this end, one further needs to code at the C++ level, as explained in the next subsection and Appendix A.1.
7.2. Adapting C++ code

There are problems which one cannot solve only by editing Mathematica model files. To unlock the full potential of FlexibleSUSY, it is an advantage not to avoid programming at the C++ level. For this, it should help to have working knowledge about the basic structure of a spectrum generator, set out in Section 6. In Appendix A, two examples are presented for demonstrating that the clean class structure serves as firm guidance on the job.

The first project in Appendix A.1 is to build a spectrum generator that can handle a tower of multiple effective field theories. The aim is to take a first step towards a study of slepton-mediated lepton flavour violation due to radiative corrections in the type-I supersymmetric see-saw model \cite{89}. To this end, MSSMRC is stacked on top of MSSMD5O. The preparation of these two models has been covered in Section 7.1.2.

Since each model class has its own $\beta$-functions, the spectrum generator contains two different sets of RGEs that are connected by a matching object. The program shall accept the low-energy neutrino masses and mixing angles which determine $\mathcal{W}_\nu$, the coefficients of the $LH_u LH_u$ operator. These $6 \times 6$ coefficients evolve to the right-handed neutrino mass scale at which they are matched to the neutrino Yukawa couplings $y_\nu$ and the right-handed neutrino masses $\nu_R$. Since there are more degrees of freedom in the pair of $y_\nu$ and $\nu_R$ than in $\mathcal{W}_\nu$, one needs supplementary conditions in addition to the see-saw relation. In the presented matching code, it is assumed that all mixing in $\mathcal{W}_\nu$ stems from the left-handed rotation of $y_\nu$ whose eigenvalues are fixed to those specified by the user. The non-trivial flavour structure of the neutrino Yukawa couplings then causes running slepton mass matrices to acquire flavour-violating elements. The output from the spectrum generator includes the slepton mass matrices as well as the resulting mass eigenvalues and mixing. One might pass this outcome on to another routine to calculate rates of lepton flavour violating processes.

For brevity, threshold corrections are ignored in the specimen matching code connecting the two models as well as in the low-scale boundary condition on $\mathcal{W}_\nu$ from the neutrino oscillation data. Therefore, the result maintains only the accuracy of one-loop RGEs, even though two-loop $\beta$-functions are computed by each model class. For a full accuracy of two-loop RGEs, one can incorporate the omitted one-loop corrections into the constraint classes. The way to implement them should be self-evident from the code structure.

The second project in Appendix A.2 shows how one can employ new spectrum generator components, which may be composed from scratch or through a linkage to external routines. In the procedure, it would be noticed that there is an evident limit on the scope of modules which one has to deal with. For instance, it is clear from the outset that one does not have to go through the code of the central fixed-point iteration engine, $\text{RGFlow}$. This manifests the power of the clear separation among objects each with its well-defined distinct role. This is just like the fact that one does not need to access the internals of the $\text{std::sort}$ function in the C++ Standard Library. It might be entertaining to complete the analogy by mapping the model objects in $\text{RGFlow}$ to the elements that $\text{std::sort}$ sorts and the boundary condition objects to the comparator function.

8. Tests and comparisons with other spectrum generators

8.1. Numeric tests

To check the correctness of FlexibleSUSY’s generated spectrum generators extensive unit testing against Softsusy’s MSSM and NMSSM implementations (both $Z_3$-invariant and $Z_3$-violating variants) has been carried out. These unit tests systematically compare all tree-level mass matrices, EWSB equations, one- and two-loop $\beta$-functions, one- and two-loop self-energies and one-
and two-loop tadpoles numerically for the CMSSM, the semi-constrained $Z_3$-invariant NMSSM ($Z_3$-NMSSM) and the constrained $Z_3$-violating NMSSM ($Z_3$-NMSSM) parameter points given in Table 2. All tested expressions were found to agree within double machine precision. Furthermore, the output of the iterative procedures which solve the one- and two-loop corrected tadpole equations \(^{[13]}\) to find the minimum of the effective Higgs potential were compared numerically for these parameter points and found to agree within machine precision as well. Finally, the overall pole mass spectrum and mixing after the full fixed-point iteration has finished has been compared, and the origin of the sub-permille level difference between FlexibleSUSY and Softsusy is the different determination of the weak mixing angle $\theta^{ \text{DR}}_{W, \text{susy}}(M_Z)$ in the SUSY model in the $\overline{\text{DR}}$ scheme: FlexibleSUSY calculates $\theta^{ \text{DR}}_{W, \text{susy}}(M_Z)$ from $M_W$ and $M_Z$, as described in Section 6.2, while Softsusy determines $\theta^{ \text{DR}}_{W, \text{susy}}(M_Z)$ from the muon decay constant $G_\mu$. The approach used in Softsusy results in more precise $\overline{\text{DR}}$ gauge couplings at the $M_Z$ scale, because the muon decay constant is known with a higher accuracy than the $W$-boson mass. Furthermore, in Softsusy 3.5.0 some three-loop $\beta$-functions and two-loop threshold corrections can be enabled in the MSSM to increase the accuracy of the RG running and the determination of the $\overline{\text{DR}}$ gauge and Yukawa couplings at $M_Z$ \(^{[90]}\). These corrections are not implemented in FlexibleSUSY so far. The complete set of unit tests is shipped with FlexibleSUSY and can be found in the test/ directory. The tests can be run with the command make execute-tests. All unit tests are carried out nightly in order to continuously check the correctness of the meta code and the generated spectrum generators for the shipped models. The nightly test results can be found at 

https://www.desy.de/~alvoigt/FlexibleSUSY/test.xhtml

The FlexibleSUSY generated NUHM E6SSM spectrum generator has also been compared against a handwritten one for a constrained version of the E6SSM \(^{[91,92,93]}\). The $\beta$-functions were

Table 2: CMSSM, semi-constrained $Z_3$-invariant NMSSM ($Z_3$-NMSSM) and constrained $Z_3$-violating NMSSM ($Z_3$-NMSSM) parameter points used for the unit tests against Softsusy.

---

5With the semi-constrained $Z_3$-invariant NMSSM ($Z_3$-NMSSM) we denote a constrained variant of the NMSSM with universal gaugino masses $M_{1/2}$, universal trilinear couplings $A_0$ and universal MSSM-like soft-breaking squared scalar masses $m_0^2$ at the GUT scale. The soft-breaking singlet mass $m_S^2$, the trilinear singlet superpotential coupling $\kappa$ and the singlet VEV $s$ are fixed by the EWSB conditions at the SUSY scale. The $Z_3$-NMSSM has the 6 free parameters ($m_0^2, M_{1/2}, A_0, \tan \beta, \text{sign} \mu_{\text{eff}}, \lambda$).

6With the constrained $Z_3$-violating NMSSM ($Z_3$-NMSSM) we denote a constrained variant of the $Z_3$-violating NMSSM with universal gaugino masses $M_{1/2}$, universal trilinear couplings $A_0$ and universal MSSM-like soft-breaking squared scalar masses $m_0^2$ at the GUT scale. The $\mu$-parameter, its soft-breaking equivalent $B_\mu$ and the soft-breaking singlet tadpole coupling $\xi_\delta$ are fixed by the EWSB conditions at the SUSY scale. The $Z_3$-NMSSM has the 11 free parameters ($m_0^2, M_{1/2}, A_0, \tan \beta, \text{sign} \mu_{\text{eff}}, \lambda, \kappa, s, \mu', m_S^2, \xi_F$).

7Due to the systematic and detailed tests several bugs in Softsusy, SARAH and FlexibleSUSY could be identified and corrected.
systematically compared in unit tests and were found to match within numerical precision. The handwritten code does not include full one-loop self-energies or tadpoles, so tests on these were not carried out. Although the generators assume different constraints and solve the boundary value problem with completely different algorithms they could be compared by using the output of the CE$_6$SSM generator as an input to FlexibleSUSY and the spectra were found to be in reasonable agreement given the different levels of precision with deviations in the mass spectra $\lesssim 10\%$.

In addition FlexibleSUSY has already undergone some user testing. This includes analytic tests of the $R$-symmetric low-energy model (MRSSM) and alternative $E_6$-inspired SUSY scenarios. The users who have helped us with this are thanked in the acknowledgements.

We also compared the run-time of FlexibleSUSY against SPheno, Softsusy and the SARAH generated MSSM spectrum generator SPhenoMSSM. The results of the comparison can be found in Section 8.2.

### 8.2. Run-time comparison

One of FlexibleSUSY’s design goals is a short run-time. In this section we demonstrate that this goal was achieved by comparing the run-time of two different sets of CMSSM spectrum generators:

- **Without sfermion flavour violation:** Disallowing sfermion flavour violation simplifies the calculation of the pole masses, because flavour-off-diagonal sfermion self-energy matrix elements do not need to be calculated. Here we compare FlexibleSUSY’s non-flavour violating CMSSM spectrum generator FlexibleSUSY-NoFV (version 1.0.0) against SPheno (version 3.2.4) and Softsusy (version 3.4.0).

- **With sfermion flavour violation:** Allowing for sfermion flavour violation in general increases the run-time of spectrum generators, because the full $6 \times 6$ sfermion self-energy matrices have to be calculated. Here we compare FlexibleSUSY-FV (version 1.0.0) and SPhenoMSSM (generated with SARAH 4.1.0 and linked against SPheno 3.2.4). Both spectrum generators are based on SARAH’s MSSM model file, which allows for sfermion flavour violation.

For the run-time comparison the CKM matrix is set to unity, all $CP$-violating phases are set to zero and $R$-parity violation is disabled. FlexibleSUSY and Softsusy are compiled with g++ 4.8.0 and Intel ifort 13.1.3 20130607. SPheno and SPhenoMSSM are compiled with Intel ifort 13.1.3 20130607. We are generating $2 \cdot 10^4$ random CMSSM parameter points with $m_0 \in [50, 1000]$ GeV, $m_{1/2} \in [50, 1000]$ GeV, $\tan \beta \in [1, 100]$, $\text{sign} \mu \in \{-1, +1\}$ and $A_0 \in [-1000, 1000]$ GeV. For each point an SLHA input file is created by appending the values of $m_0$, $m_{1/2}$, $\tan \beta$, $\text{sign} \mu$, $A_0$ in form of a MINPAR block to the SLHA template file given in Appendix B. The resulting SLHA input file is passed to each spectrum generator and the (wall-clock) time is measured until the program has finished. The average run-times for three different CPU types can be found in Table 3. The first column shows the run-time on an Intel Core2 Duo (P8600, 2.40 GHz) where only one core was enabled. The second column shows the run-time on the same processor where both cores were enabled. In the third column a machine with two Intel Xeon CPUs (L5640, 2.27 GHz, 6 cores) was used.

---

8 Intel’s ifort compiler decreases the run-time of SPheno and SPhenoMSSM by approximately a factor 1.5, compared to gfortran.

Table 3: Average run-time of CMSSM spectrum generators for random parameter points. The first three rows show three spectrum generators with disabled sfermion flavour violation. Rows 4–5 show two spectrum generators with enabled sfermion flavour violation, both based on SARAH’s MSSM model file.

Among both the non-flavour violating spectrum generators (first three rows) as well as the flavour violating ones (4th and 5th row) we find that FlexibleSUSY is significantly fastest. Compared to SPheno, FlexibleSUSY-NoFV is faster by a factor 1.4–1.7, and compared to Softsusy around a factor 2–2.5. Between the flavour violating spectrum generators FlexibleSUSY-FV is faster than SPhenoMSSM by a factor 2.8–5. Reason for the long run-time of SPhenoMSSM is the long calculation duration of the two-loop $\beta$-functions. Here FlexibleSUSY benefits a lot from Eigen’s well-optimizable matrix expressions. We also find that increasing the number of CPU cores reduces the run-time of FlexibleSUSY. The reason is that FlexibleSUSY calculates each pole mass in a separate thread, and therefore benefits from multi-core CPUs.

9. Conclusions

We have presented FlexibleSUSY, a Mathematica and C++ package, which generates fast and modular spectrum generators for any user specified SUSY model. FlexibleSUSY is distributed with a large number of predefined models for the CMSSM, NMSSM, USSM, $E_6$SSM, MRSSM etc., which can be generated immediately without any editing. In particular the CMSSM and NMSSM spectrum generators constitute a fast and reliable alternative to the existing publicly available spectrum generators, Softsusy, SPheno and NMSPEC.

We have described how the generated source code can be influenced at two different levels: The Mathematica level where the user provides a model file, and the C++ level where the generated objects can be easily exchanged, extended, modified and reused. This provides great flexibility for creating custom spectrum generators for both the most common and most extraordinary models. We have demonstrated these features in detailed examples for the NUHMSSM, right handed neutrinos and on adding three-loop RGEs and two-loop matching for the strong gauge coupling.

The generated code has been extensively tested against Softsusy, and additional tests have been carried out for non-minimal models, the $E_6$SSM and MRSSM. Speed tests have also been performed against Softsusy, SPheno and SPheno-like MSSM code generated by SARAH, demonstrating that FlexibleSUSY runs faster than all three.

As a result FlexibleSUSY enables fast exploitation of new SUSY models with high precision and reliability.
**Appendix A. Examples of C++ code adaptation**

In what follows, technical details of FlexibleSUSY programming at the C++ level are set out which supplement the outline given in Section 7.2.

**Appendix A.1. Stacking models in a tower of effective theories**

Consider a physics scenario which is best described by a tower of effective theories. Within the framework of FlexibleSUSY, the C++ class structure is a faithful reflection of this physicist’s view on the given problem. Here we illustrate this point using a well-known configuration in which the higher-energy theory is the MSSMRHN which gives rise to the MSSMD5O as the lower-energy effective theory. The relevant classes are sketched in Figure A.3. The MSSMRHN object is in effect from the $M_X$ scale down to the $M_\nu$ scale at which the right-handed neutrinos are decoupled. Below this scale, the MSSMD5O object takes over. On the left of the vertical axis, the boundary condition objects acting on either model are displayed, together with the matching object connecting the two theories. Note that each of the boundary condition and matching objects maintains and updates

![Figure A.3: Schematic class structure in the C++ code for the tower scenario.](image-url)
its own scale over iterations. An arrow in the figure depicts the association of a constraint with its scale. All these components are plugged into the _RGFlow_ object which then solves the problem.

The matching class as well as gluing codes have to be written by hand to build such a program. All remaining components of a multi-model spectrum generator can be authored by making a straightforward extension to each corresponding single-model counterpart for one of the models forming the tower.

As the target spectrum generator depends on two models, one should first build these prerequisites by:

```bash
1 $ ./createmodel --name=MSSMD50
2 $ ./createmodel --name=MSSMRHN
3 $ ./configure --with-models=MSSMD50,MSSMRHN
4 $ make
```

As a by-product, line 3 also creates a Makefile in examples/tower/. One can best see the overall code structure of the application in this file:

```c
1 CPPFLAGS := -I. $(INCCONFIG) $(INCFLEXI) $(INCLEGACY) $(INCSLHAEA) \ 2 $(INCMSSMD50) $(INCMSSMRHN)
3
4 TOWER_SRC := run_tower.cpp \ 5 MSSMD50_MSSMRHN_two_scale_matching.cpp \ 6 MSSMD50_MSSMRHN_two_scale_initial_guesser.cpp
7
8 TOWER_OBJ := $(patsubst %.cpp, %.o, $(filter %.cpp, $(TOWER_SRC)))
9
10 run_tower.x: $(TOWER_OBJ) $(LIBMSSMD50) $(LIBMSSMRHN) $(LIBFLEXI) $(LIBLEGACY) \ 11 $(CXX) -o $@ $(LODFUNCLIBS) $(GLSLIBS) $(BOOSTTHREADLIBS) $(THREADLIBS) \ 12 $(LAPACKLIBS) $(BLASLIBS) $(FLIBS)
```

The include directives in line 2 tell the compiler where to find the headers for either _MSSMD50_ or _MSSMRHN_. The .cpp files in lines 4–6 and the .hpp files that they include are to be written by hand. Obviously, the executable _run_tower.x_, in line 10, depends on both $(LIBMSSMD50) and $(LIBMSSMRHN) that implement the auto-generated components in Figure A.3.

To prepare the main source file _run_tower.cpp_, one can extend _run_MSSMD50.cpp_ or _run_MSSMRHN.cpp_ produced in either model directory. The shipped example reads:

```c
1 #include "MSSMD50_MSSMRHN_spectrum_generator.hpp"
2 int main(int argc, char* argv[])
3 {
4     // define objects;
5     QedQcd onesub;
6     MSSMD50_input_parameters input_1;
7     MSSMRHN_input_parameters input_2;
8     // fill in input_1 and input_2;
9     onesub.toMz(); // run SM fermion masses to MZ
10     typedef Two_scale algorithm_type;
```

---

^It is planned that a future release of FlexibleSUSY will be capable of creating this code automatically.
where a line in the form // ...; shall be understood to be a pseudo-code. Given two models, one declares two sets of input parameters, \texttt{input\_1} and \texttt{input\_2}, in lines 7–8.

The crucial point is the definition of the \texttt{MSSMD50\_MSSMRHN\_spectrum\_generator} object in line 12, which creates and drives the \texttt{RGFlow} object in Figure \[A.3] This task is started by calling the \texttt{run()} member function in line 14. It is defined in \texttt{MSSMD50\_MSSMRHN\_spectrum\_generator.hpp} and reads:

```cpp
template<class T> void MSSMD50_MSSMRHN_spectrum_generator<T>::run(
    const QedQcd& onese, 
    const MSSMD50_input_parameters& input_1, const MSSMRHN_input_parameters& input_2)
{
    high_scale_constraint_2.clear(); // of type MSSMRHN_high_scale_constraint<T>
    susy_scale_constraint_1.clear(); // of type MSSMD50_susy_scale_constraint<T>
    low_scale_constraint_1.clear(); // of type MSSMD50_low_scale_constraint<T>
    matching.reset(); // of type MSSMD50_MSSMRHN_matching<T>
    high_scale_constraint_2.set_input_parameters(input_2);
    susy_scale_constraint_1.set_input_parameters(input_1);
    low_scale_constraint_1.set_input_parameters(input_1);
    matching.set_lower_input_parameters(input_1);
    high_scale_constraint_2.initialize();
    susy_scale_constraint_1.initialize();
    low_scale_constraint_1.initialize();
    if (!is_zero(input_scale_2)) high_scale_constraint_2.set_scale(input_scale_2);
}
```

This piece of code is nearly a verbatim copy of the corresponding part of \texttt{MSSMD50\_spectrum\_generator.hpp}. The only differences are that the type of \texttt{high_scale_constraint\_2} is \texttt{MSSMRHN\_high\_scale\_constraint<T>} and that the \texttt{matching} object has been added. Recall that the template parameter \texttt{T} has been bound to \texttt{Two\_scale} in the main function. One then constructs a list of the constraints on \texttt{MSSMD50}:

```cpp
std::vector<Constraint<T>*> upward_constraints_1;
upward_constraints_1.push_back(&low_scale_constraint_1);
std::vector<Constraint<T>*> downward_constraints_1;
downward_constraints_1.push_back(&susy_scale_constraint_1);
downward_constraints_1.push_back(&low_scale_constraint_1);
```

and initializes the \texttt{MSSMD50} object:

```cpp
model_1.clear(); // of type MSSMD50<T>
model_1.set_input_parameters(input_1);
model_1.do_calculate_sm_pole_masses(calculate_sm_masses);
```

Likewise for \texttt{MSSMRHN}:

```cpp
std::vector<Constraint<T>*> upward_constraints_2;
upward_constraints_2.push_back(&high_scale_constraint_2);
```
Note that model\(_2\) does not have to calculate the pole masses of the SM particles since it is active only above \(M_\nu\) which is assumed to be much higher than the weak scale. To test the convergence of both models, one may construct a composite convergence tester out of auto-generated MSSMD50\_convergence\_tester and MSSMRHN\_convergence\_tester:

```cpp
MSSMD50\_convergence\_tester\<\text{T}\> convergence\_tester\_1 (\&model\_1, precision\_goal);
MSSMRHN\_convergence\_tester\<\text{T}\> convergence\_tester\_2 (\&model\_2, precision\_goal);
if (max\_iterations > 0) {
    convergence\_tester\_1.set\_max\_iterations(max\_iterations);
    convergence\_tester\_2.set\_max\_iterations(max\_iterations);
}
Composite\_convergence\_tester\<\text{T}\> convergence\_tester;
convergence\_tester.add\_convergence\_tester(\&convergence\_tester\_1);
convergence\_tester.add\_convergence\_tester(\&convergence\_tester\_2);
```

On construction, the initial guesser accepts the following parameters including the two model objects:

```cpp
MSSMD50\_MSSMRHN\_initial\_guesser\<\text{T}\> initial\_guesser
(\&model\_1, \&model\_2, input\_1, oneset,
 low\_scale\_constraint\_1, susy\_scale\_constraint\_1, high\_scale\_constraint\_2,
 matching);
```

The code of the above class shall be presented later on. One then passes convergence\_tester and initial\_guesser to solver, the RGFlow object, along with the precision specification:

```cpp
Two\_scale\_increasing\_precision precision(10.0, precision\_goal);
solver.reset(); // of type RGFlow\<\text{T}\>
solver.set\_convergence\_tester(\&convergence\_tester);
solver.set\_running\_precision(\&precision);
solver.set\_initial\_guesser(\&initial\_guesser);
```

Finally, one is ready to construct the tower of effective theories by adding to solver each model plus the associated list of constraints optionally accompanied by a matching object:

```cpp
solver.add\_model(\&model\_1, \&matching, upward\_constraints\_1, \\
   downward\_constraints\_1);
solver.add\_model(\&model\_2, upward\_constraints\_2, downward\_constraints\_2);
```

The order of addition is from the lowest scale to the highest. Notice in line 49 that the matching object between model\(_1\) and model\(_2\) is given when one adds the former, i.e. the lower-energy model. It then remains to solve the boundary value problem:

```cpp
high\_scale\_2 = susy\_scale\_1 = low\_scale\_1 = 0; matching\_scale = 0;
```
After the solution is found, one can obtain the resulting low-energy spectrum. Since `model_1` is in contact with the lowest energy, let it calculate the spectrum:

```
susy_scale_1 = susy_scale_constraint_1.get_scale();
model_1.run_to(susy_scale_1);  // of type MSSM5O<T>
model_1.calculate_spectrum();
if (!is_zero(parameter_output_scale_1))
    model_1.run_to(parameter_output_scale_1);
```

In lines 56–57, the scale is optionally brought to the value at which one wishes to get the DR parameters.

One needs to write the matching class for a particular pair of models from scratch. It shall be based on the abstract class `Matching<Two_scale>` that comes with FlexibleSUSY. In the present example, the class is declared in the header `MSSM5O_MSSMRHN_two_scale_matching.hpp`:

```cpp
template<> class MSSM5O_MSSMRHN_matching<Two_scale> : public \
    Matching<Two_scale> {
public:
    MSSM5O_MSSMRHN_matching();
    MSSM5O_MSSMRHN_matching(const MSSM5O_input_parameters&);
    void match_low_to_high_scale_model();
    void match_high_to_low_scale_model();
    double get_scale() const;
    void set_models(Two_scale_model *lower, Two_scale_model *upper);
    double get_initial_scale_guess() const;
    void set_lower_input_parameters(const MSSM5O_input_parameters&);
    void set_scale(double);
    void reset();
private:
    MSSM5O<Two_scale> *lower;
    MSSMRHN<Two_scale> *upper;
    void make_initial_scale_guess();
    void update_scale();
    ...
};
```

As lines 4 and 10 indicate, this class takes an `MSSM5O_input_parameters` object as input. The low-energy neutrino data therein is referenced by `make_initial_scale_guess` starting from line 23 of `MSSM5O_MSSMRHN_two_scale_matching.cpp`:

```cpp
void MSSM5O_MSSMRHN_matching<Two_scale>::invert_seesaw_formula
(const Eigen::Matrix3d& WOp, const Eigen::Vector3d& YvDiag,
 Eigen::Matrix3d& Yv, Eigen::Matrix3d& Mv) {
    Eigen::Matrix3cd uh;
    Eigen::Array3d s;
    fs_diagonalize_symmetric(WOp, s, uh);
    Eigen::Matrix3d U = uh.adjoint().real();
```
To guess the matching scale, this function estimates the right-handed neutrino mass matrix $Mv$ from $WOp$, the dimension-5 operator coefficients, and $YvDiag$, the neutrino Yukawa eigenvalues, by calling `invert_seesaw_formula`. Since the mapping, $WOp \rightarrow (Yv, Mv)$, is not unique, `invert_seesaw_formula` opts to impose the following additional constraints: the eigenvalues of $Yv$ are fixed to the user input (line 10), and all mixing in $WOp$ originates from the rotation of the SU(2) doublets (line 11).

The actual matching process takes place in the two functions `match_low_to_high_scale_model` and `match_high_to_low_scale_model`:
```cpp
const auto & Yv = upper -> get_Yv ();
const auto & Mv = upper -> get_Mv ();
lower -> set_WOp(Yv . transpose () * Mv . inverse () * Yv);
lower -> set_Yd ( upper -> get_Yd ());
// copy rest of couplings from upper to lower;
lower -> set_scale ( upper -> get_scale ());
}

void MSSMD5O_MSSMRHN_matching<Two_scale>::update_scale ()
{
    double RHN_scale = pow ( abs ( upper -> get_Mv () . determinant () ) , 1.0/3) ;
scale = RHN_scale ;
}
```

For the low-to-high matching, `invert_seesaw_formula` is called in line 7, this time with `WOp` at the matching scale. The high-to-low matching function contains the well-known see-saw formula in line 22. The matching scale is updated at each iteration to be the geometric mean of the running `Mv` eigenvalues in lines 31–32.

The last missing piece is the initial guesser. One can extend the already available `MSSMD5O_initial_guesser` class. The essential task is done by the following member function:

```cpp
void MSSMD5O_MSSMRHN_initial_guesser<Two_scale>::guess ()
{
    // guess SUSY couplings in model-1 at low energy;
    const double low_scale_guess_1 = low_constraint_1 . get_initial_scale_guess();
    const double high_scale_guess_2 = high_constraint_2 . get_initial_scale_guess();
    const double matching_scale_guess = matching . get_initial_scale_guess();
```

Compared to the MSSMD5O case, the differences are that the type of `high_constraint_2` is `MSSMRHN_high_scale_constraint<Two_scale>` and that `matching_scale_guess` has been inserted. Due to this intermediate scale, the initial run-up is divided into two steps, with a matching procedure in-between:

```cpp
model_1 -> run_to ( matching_scale_guess ); // of type MSSMD5O<Two_scale>
matching . set_models ( model_1 , model_2 );
matching . match_low_to_high_scale_model ();
model_2 -> run_to ( high_scale_guess_2 ); // of type MSSMRHN<Two_scale>
```

The high-scale constraints are applied to `model_2`, the higher-energy model, and the remaining undetermined parameters are guessed:

```cpp
high_constraint_2 . set_model ( model_2 );
high_constraint_2 . apply ();
model_2 -> set_Mu (1.0); model_2 -> set_BMu (0.0);
```

The initial two-step run-down again involves a matching process:

```cpp
model_2 -> run_to ( matching_scale_guess );
```
At the low scale where MSSM50 is valid, the code is the same as in MSSM50_initial_guesser:

```
model_1->solve_ewsb_tree_level();
model_1->calculate_DRbar_masses();
model_1->set_thresholds(3); model_1->set_loops(2);
```

```
Finally, one prescribes the additional input parameters in the SLHA input file:

```
<table>
<thead>
<tr>
<th>Block EXTPAR # Input parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 5.0E-11 # mv1</td>
</tr>

```

This result demonstrates the well-known effect on the off-diagonal slepton mass matrix elements from a non-trivial flavour structure of $Y_{v}$ [89]. This leads in turn to the slepton mixing matrices, $Z_{E}$ and $Z_{V}$, which contain inter-generational mixings apart from the generic left-right mixings.
Appendix A.2. Integrating custom-built C++ components

In Section 7.1.1, it was explained how one can let FlexibleSUSY generate an alternative boundary condition class by authoring a model file. Nonetheless, the way to employ this class at the C++ level might still remain obscure to the reader since FlexibleSUSY automatically took care of it. Here, an example shall be exhibited with the emphasis on the modular C++ code structure that helps such programming tasks. Concretely, the auto-generated low-energy boundary condition on the MSSM shall be modified so that $\alpha^\text{DR}_{s,\text{susy}}$ is determined from $\alpha^\text{(5)MS}_{s,\text{SM}}$ by means of a two-loop matching. This shall be accompanied by an improvement of the $g_3$ $\beta$-function to the three-loop accuracy.

The first step is to alter the model class which evaluates the $\beta$-functions. Thanks to the beta() method being virtual, one can override it conveniently by deriving a class from MSSM. The declaration might look like:

```cpp
#include "MSSM_two_scale_model.hpp"

template <>
class MSSMcbs<Two_scale> : public MSSM<Two_scale> {
public:
  explicit MSSMcbs(const MSSM_input_parameters& input_=MSSM_input_parameters());
  virtual ~MSSMcbs();
  virtual Eigen::ArrayXd beta() const;
  MSSM_soft_parameters calc_beta() const;
};
```

where the name MSSMcbs is an abbreviation of the MSSM with custom-built $\beta$’s. Note that the objects for MSSM are reused where possible: MSSM_input_parameters in line 6 as well as MSSM_soft_parameters in line 9. This saves the programmer from excessive duplication of codes. The member function definitions read:

```cpp
Eigen::ArrayXd MSSMcbs<Two_scale>::beta() const
{
  return calc_beta().get();
}
MSSM_soft_parameters MSSMcbs<Two_scale>::calc_beta() const
{
  MSSM_soft_parameters betas(MSSM<Two_scale>::calc_beta());
  if (get_loops() <= 2) return betas;
  double bg33 = /* formula in terms of g1, g2, g3, Yu, Yd, Ye */;
  betas.set_g3(betas.get_g3() + Power(oneOver16PiSqr,3) * g3 * bg33);
  return betas;
}
```

The full C++ expression of $bg33$, used in MSSMcbs_two_scale_model.cpp, has been adapted from the code by Jack and Jones [94]. This already completes the amendment of the $g_3$ $\beta$-function.

The next step is to write a substitute for the low-energy boundary condition class. It must be declared as a descendant of Constraint<Two_scale> whose function is described in Section 6.2.
template <>
class MSSMcbs_low_scale_constraint<Two_scale> : public Constraint<Two_scale> {
public:
  MSSMcbs_low_scale_constraint(const MSSM_input_parameters&, const QedQcd&);
  virtual ~MSSMcbs_low_scale_constraint();
  void set_threshold_corrections(unsigned);
...
private:
  MSSMcbs<Two_scale>* model;
  QedQcd oneset;
  double new_g3;
  unsigned threshold_corrections;
  void calculate_DRbar_gauge_couplings();
  double calculate_alS5DRbar_over_alS5MSbar(double) const;
  double calculate_zeta_g_QCD_2(double) const;
  double calculate_zeta_g_SUSY_2(double) const;
...
};

In line 11, the type of model has been adapted to the new model. In fact, this class should work even if model remained a pointer to MSSM<Two_scale> because of inheritance. The main additions to MSSM_low_scale_constraint in models/MSSM/ are the member functions in lines 16–18, which evaluate the two-loop matching coefficients from Ref. [95]. The following member function then performs the two-step decoupling as reported in this reference:

```c++
void MSSMcbs_low_scale_constraint<Two_scale>::calculate_DRbar_gauge_couplings()
{
  ...
  double alpha_s = oneset.displayAlpha(ALPHAS);
  double alS5DRbar_over_alS5MSbar = 1;
  double zeta_g_QCD_2 = 1;
  double zeta_g_SUSY_2 = 1;
  if (model->get_thresholds()) {
    alS5DRbar_over_alS5MSbar = calculate_alS5DRbar_over_alS5MSbar(alS5DRbar_over_alS5MSbar);
    alpha_s *= alS5DRbar_over_alS5MSbar; // alS5MSbar -> alS5DRbar
    zeta_g_QCD_2 = calculate_zeta_g_QCD_2(zeta_g_QCD_2);
    alpha_s /= zeta_g_QCD_2; // alS5DRbar -> alS6DRbar
    zeta_g_SUSY_2 = calculate_zeta_g_SUSY_2(zeta_g_SUSY_2);
    alpha_s /= zeta_g_SUSY_2; // alS6DRbar -> alS6DRbarMSSM
    ...
  }
  new_g3 = Sqrt(4*Pi * alpha_s);
  ...
}
```

Finally, one can integrate the new boundary condition class MSSMcbs_low_scale_constraint together with the new model MSSMcbs into the spectrum generator in a straightforward manner. They should supersede MSSM_low_scale_constraint and MSSM, respectively. The replacement should be carried out in those objects that depend on these classes, i.e. the initial guesser:

```c++
template <>
```
class MSSMcbs_initial_guesser<Two_scale> : public Initial_guesser<Two_scale> {
public:
  MSSMcbs_initial_guesser(MSSMcbs<Two_scale>*,
    const MSSM_input_parameters&,
    const QedQcd&,
    const MSSMcbs_low_scale_constraint<Two_scale>&,
    const MSSM_susy_scale_constraint<Two_scale>&,
    const MSSM_high_scale_constraint<Two_scale>&);
...
private:
  MSSMcbs<Two_scale>* model;
  MSSM_input_parameters input_pars;
 QedQcd oneset;
  MSSMcbs_low_scale_constraint<Two_scale> low_constraint;
  MSSM_susy_scale_constraint<Two_scale> susy_constraint;
  MSSM_high_scale_constraint<Two_scale> high_constraint;
...};

as well as the spectrum generator object:

template <class T>
void MSSMcbs_spectrum_generator<T>::run(const QedQcd& oneset,
  const MSSM_input_parameters& input)
{
...
  MSSMcbs_initial_guesser<T> initial_guesser
    (&model, input, oneset,
     low_scale_constraint, susy_scale_constraint, high_scale_constraint);
...}

One can find a working realization of this example in examples/customized-betas/.
