We apply the Jeffrey-Kirwan method to compute the multiple integrals for the $BCD$-type Nekrasov partition functions of four-dimensional $\mathcal{N} = 2$ supersymmetric gauge theories. We construct a graphical distinction rule to determine which poles are surrounded by their integration cycles. We compute the instanton correction of the “$Sp(0)$” pure super-Yang–Mills theory and find that $Z^{Sp(0)}_k = (-1)^k / 2^k k! \epsilon_1^k \epsilon_2^k$ for $k \leq 8$, which resembles the formula $Z^{U(1)}_k = (k! \epsilon_1^k \epsilon_2^k)^{-1}$ for the pure super-Yang–Mills theory with gauge group $U(1)$.

1. Introduction and summary

From the advent of Seiberg–Witten curves [1], many works began to appear in order to pursue non-perturbative aspects of supersymmetric gauge theories. In particular, it was found that instanton corrections can be calculable for some theories. Nekrasov and others derived instanton partition functions, or Nekrasov partition functions, for four-dimensional $\mathcal{N} = 2$ gauge theories [2,3]. They applied a localization method to instanton moduli spaces and gave the partition functions by finite-dimensional integrations when the gauge groups are classical.

When the gauge group is unitary, however, one can avoid direct evaluations of the integral. The $U(1)$ Nekrasov partition function can be rephrased in terms of Hilbert schemes of points on surfaces [4,5] and expressed by a sum over Young diagrams, whose summands can be given by an algebraic manipulation of such diagrams. Each Young diagram corresponds to a fixed point in the instanton moduli space with respect to the localization, and its summand means its weight. Similarly, the $SU(N)$ Nekrasov partition function can be expressed as a sum over fixed points, or $N$-vectors of Young diagrams [2,6,7]. In terms of integrations, each fixed point corresponds to a $S_N$-orbit of poles of the integrand whose sum of residues does not vanish.

Later, the Alday–Gaiotto–Tachikawa (AGT) relation [8] was proposed, which implies that there exists an action of an infinite-dimensional nonlinear symmetry, which is of a two-dimensional conformal field theory, on (the fixed points of) the instanton moduli space in four dimensions. This relation has been proved for some $SU(N)$ gauge theories [9–16]. The fixed points mentioned above have played the role of a good basis where such actions can be seen easily, like simultaneous eigenstates of a Cartan subalgebra of a simple Lie algebra, and been used to construct a certain coherent vector of the nonlinear symmetry.

Taking these results for the unitary gauge group, it may be useful to identify the set of all the fixed points in an instanton moduli space to see how the AGT relation works when the gauge group
is general. However, the techniques used in the unitary case do not work well for the other gauge groups. To the best of our knowledge, one has to evaluate their integrals directly when one identifies the set of fixed points for the $SO(N)$ or $Sp(N)$ cases. Much effort has been made for these cases [7,18–20], but has been limited to small instanton numbers.

This limitation may stem not only from the troublesome calculations of their multiple integrations but also from a subtle issue of multiple integrations—the contour choice. For the Nekrasov partition function with one integral variable, the contour lies in the real axis and surrounds the upper half-plane. This expression fixes the integration cycle and then one can perform the integration using Cauchy’s formula. Similarly for the partition function with multiple variables, each variable is real and tends to surround the upper half-plane. However, this expression is too naive to identify an integration cycle because one may treat a pole whose (iterated) residue depends on how to surround it. In other words, one should be careful in expanding an integrant of several variables to get its Laurent series. Also, there may be a pole whose component is real, which means that it is unclear whether the pole is “in” or “out” of the integration cycle. In the author’s previous paper [21], such unclear poles as well as awkward cancellations of residues appeared after regarding the multiple integral as an iterated integral. These difficulties have motivated the author to construct a better algorithm to compute the integrals representing the Nekrasov partition functions.

Then, when one tackles a multiple contour integral, one has to specify its integration cycle more clearly. For our cases, the cycle must be determined physically. In recent years, the authors of [22–24] considered the choice and showed that the Jeffrey–Kirwan (JK) residue operator [25] gives the true cycles in the multiple integration expressions for the Nekrasov partition functions.

Therefore, in this paper, we consider how this JK-residue method works for the $BCD$-type Nekrasov partition functions. We construct a graphical algorithm to determine which poles are in the integration cycle and partly calculate the partition function for the “$Sp(0)$” case. As a result, we get the resultant list of residues in Appendix A and observe

$$Z_k^{Sp(0)} = \frac{(-1)^k}{2^k k! \epsilon_1 \epsilon_2} \quad (k \leq 8) \quad (1.1)$$

---

1 The AGT relations for 1-instantons were considered in [17]. In this case, one can determine all the weights of fixed points without using integral expressions.

2 In particular, for the $SO(N)$ or $Sp(N)$ cases, some analogies of the stability condition in [4] for the unitary cases seem to be needed, but they are not known at present.

3 For example, we have different results from two different cycles:

$$\frac{1}{x(y - x)} \mapsto \frac{1}{y} \mapsto 1,$$

$$\frac{1}{x(y - x)} \mapsto 0 \mapsto 0.$$ These results depend on whether the contour that the variable $x$ goes through contains the one for the variable $y$. We should split the two circles and determine an integration cycle.

4 The graphical algorithm concerns the “multiplicities” of poles in [20]. The notion of the multiplicity may arise from the choice of the integration cycle. The pole distribution of the integrand is symmetric under a Weyl group, but the integration cycle may break this symmetry. Then, for a given Weyl orbit of some poles, it is unclear how many poles in the orbit contribute to the partition function. Roughly speaking, the multiplicity for the orbit is the number of its poles in the cycle. The graphical algorithm determines such numbers.
for the $Sp(0)$ case, which coincides with the Taylor expansion of $\exp \left( -q/2\varepsilon_1\varepsilon_2 \right)$ at $q = 0$. This resembles $Z_k^{U(1)} = \left( k! \varepsilon_1^k \varepsilon_2^k \right)^{-1}$ for the $U(1)$ case. In the latter $U(1)$ case, it can be rephrased as a combinatorial formula of Jack polynomials, whose algebraic properties give clearer understandings of the partition function and lead to the AGT proofs for some unitary cases. Then our observation for the $Sp(0)$ case implies some algebraic backgrounds of its partition function and may become a key to proving the AGT relations for the $BCD$ cases through the construction of a representation of an infinite-dimensional algebra acting on some orthogonal polynomials.

We organize this paper as follows. In Sect. 2, we first review the Nekrasov partition functions and the JK-residue operator and then consider a sum of residues over a Weyl orbit of poles, representing a key to proving the AGT relations for the $BCD$ for the partition function and lead to the AGT proofs for some unitary cases. Then our observation combinational formula of Jack polynomials, whose algebraic properties give clearer understandings of some related materials that we do not treat in this paper.

2. Nekrasov partition function and Jeffrey–Kirwan residue

In this section, we first recall the integral expressions of the Nekrasov partition functions and pick up some aspects of the Jeffrey–Kirwan residue. Then we rewrite the Nekrasov partition functions into the summation over all the Weyl orbits of poles in their integrands. We will use the final form (2.25) in the following sections.

2.1. Nekrasov partition function

The nonperturbative correction of the partition function for an $\mathcal{N} = 2$ supersymmetric gauge theory on the $\Omega$-deformed $\mathbb{R}^4$, called the Nekrasov partition function, can be represented as a multiple integral when the gauge group $G$ of the theory is classical [2,18]. Here we trace how it was derived and explain why we compute the partition function by another way.\(^5\)

One can lift a four-dimensional $\mathcal{N} = 2$ supersymmetric gauge theory on the spacetime $\mathbb{R}^4$ to a five-dimensional $\mathcal{N} = 1$ supersymmetric gauge theory on $\mathbb{R}^4 \times S^1, \beta$, where the $\beta$ means the circumference of the circle $S^1$. The $\Omega$-background is translated as the boundary condition $(z_1, z_2, y + \beta) \sim (e^{i\varepsilon_1 z_1}, e^{i\varepsilon_2 z_2}, y) \left[ (z_1, z_2) \in \mathbb{C}^2 \simeq \mathbb{R}^4, y \in S^1 \right]$. In the weak 5d gauge coupling limit, or $\beta \to 0$, the $k$-instanton sector of the theory reduces to a supersymmetric quantum mechanics whose target space is the finite-dimensional $k$-instanton moduli space $\mathcal{M}_k$ [26]. Then the $k$-instanton partition function $Z_k^{(5d)}$ for this 5d theory is given by the index

$$Z_k^{(5d)} = \text{Tr}_{\mathcal{H}_k} (-1)^F e^{-\beta H} e^{i\beta (\varepsilon_1 J_1 + \varepsilon_2 J_2)} e^{i\beta a_j \Pi^j} e^{i\beta u K}, \quad (2.1)$$

where $\mathcal{H}_k$ is the Hilbert space of the quantum mechanics, $J_{1,2}$ are the generators of the Cartan algebra of $SO(4)$, $\Pi^j$ is the charge coupling to the vacuum expectation value $a_j$ of the adjoint scalar in the vector multiplet, and $K$ is the charge of the other global symmetry in the quantum mechanics.

---

\(^5\) This box description is not new. It appeared in [19,20].

\(^6\) One may skip the following explanation if one assumes that the integration cycle that appears in the Nekrasov partition function is the one that the Jeffrey–Kirwan residue operator gives.
which couples with the parameter $u$. Taking the $\beta \to 0$ limit, $Z_k^{(5d)}$ reduces to the Nekrasov partition function $Z_k$ for the 4d theory with instanton number $k$.

This index can be written by an integral over the target space as a result of the index theory. Moreover, if the gauge group is classical, one can parametrize the instanton moduli spaces by the ADHM matrices \cite{27}, constrained by the ADHM equation and by the action of the inner symmetry group $\hat{G}$ of instantons. If the target space were a smooth manifold, one could apply the localization method to this parametrized manifold. Then, one can find all the fixed points with respect to the global symmetry that appears in (2.1) and evaluate their weights around the fixed points. These data allow one to perform the localization explicitly and then one reaches the integral expressions of the instanton partition functions whose integration variables come from the maximal torus of $\hat{G}$. In the 4d limit $\beta \to 0$, each integration variable surrounds the upper half-plane. The positive imaginary parts with coefficients like $\epsilon_{1,2}$ are imposed for the convergence of the index (2.1).

In particular, for a pure super-Yang–Mills theory (SYM) with gauge group $G$, the Nekrasov partition function $Z_k^G$ is written explicitly as follows \cite{2,18}.

**Example (Nekrasov partition functions for pure SYM theories)**

(i) For $G = U(N)$,

$$
Z_k^{U(N)} = \frac{1}{k!} \left( \frac{\epsilon}{2\pi i} \right)^k \int \frac{d\phi_1 \cdots d\phi_k}{\prod_{j=1}^k P(\phi_j - \epsilon_+) P(\phi_j + \epsilon_+)} \frac{\Delta(0) \Delta(\epsilon)}{\Delta(\epsilon_1) \Delta(\epsilon_2)},
$$

where $\epsilon = 2\epsilon_+ = \epsilon_1 + \epsilon_2$, $P(x) = \prod_{i=1}^N (x - a_i)$, and $\Delta(x) = \prod_{i < j} \left( (\phi_i - \phi_j)^2 - x^2 \right)$.

(ii) For $G = SO(N)$ with $N = 2n + \chi (n \in \mathbb{N}, \chi = 0, 1)$,

$$
Z_k^{SO(N=2n+\chi)} = \frac{(-1)^{k(N+1)}}{2^k k!} \left( \frac{\epsilon}{2\pi i} \right)^k \int \frac{d\phi_1 \cdots d\phi_k}{\prod_{j=1}^k P(\phi_j - \epsilon_+) P(\phi_j + \epsilon_+)} \frac{\Delta(0) \Delta(\epsilon)}{\Delta(\epsilon_1) \Delta(\epsilon_2)},
$$

where $P(x) = x^2 \prod_{i=1}^n (x^2 - a_i^2)$ and $\Delta(x) = \prod_{i < j} \left( (\phi_i - \phi_j)^2 - x^2 \right) \left( (\phi_i + \phi_j)^2 - x^2 \right)$.

(iii) For $G = Sp(N)$ with $k = 2n + \chi (n \in \mathbb{N}, \chi = 0, 1)$,

$$
Z_k^{Sp(N)} = \frac{(-1)^n}{2^{2n-1} n!} \left( \frac{\epsilon}{2\pi i} \right)^n \frac{1}{\epsilon_1 \epsilon_2} \int \frac{d\phi_1 \cdots d\phi_n}{\prod_{j=1}^n P(\phi_j - \epsilon_+) P(\phi_j + \epsilon_+)} \frac{\Delta(0) \Delta(\epsilon)}{\Delta(\epsilon_1) \Delta(\epsilon_2)},
$$

where $P(x) = \prod_{i=1}^n (x^2 - a_i^2)$ and $\Delta(x) = \prod_{i < j} \left( (\phi_i - \phi_j)^2 - x^2 \right) \left( (\phi_i + \phi_j)^2 - x^2 \right)$.

However, this expression is inconvenient for seeking a combinational formula for the Nekrasov partition function, which is already known for the case $G = U(N)$ \cite{2,6,7}. To get a combinational formula, one will need to specify which poles are in the integration cycle. Each fixed point appearing in the localization of the moduli space corresponds to a class of such poles. For $G = SO(N)$, $Sp(N)$, however, there are poles whose components are real and it is unclear whether such poles are in or out the cycles.\footnote{For example, there is a pole at $(\phi_1, \phi_2) = (\epsilon_1, 0)$ when one considers the 4-instanton correction for the case $G = Sp(N)$.} It is desirable to get such a combinational expression not only because we can compute
the partition function easily, but also because it was found to be useful to understand the action of an infinite-dimensional symmetry to the instanton moduli space, which results in the proof of the AGT relation [8] for some theories with unitary gauge group [9–16].

This obstruction to getting the sum of residues may stem from the fact that the instanton moduli spaces are generally singular. There are UV singularities where two small instantons approach each other and IR singularities where an instanton goes far away. The latter singularities are resolved by the \( \Omega \)-background and then we have to resolve the UV singularities. In fact, the known combinational formula for the case with unitary gauge group can be achieved by resolving these singularities [4,5].

One way to resolve the UV singularities is to lift the quantum mechanics to the gauged linear sigma model (GLSM) with gauge group \( \hat{G} \), the internal symmetry of instantons, by adding a vector multiplet to the original matter multiplets. In the limit when the coupling constant \( g_{QM} \) of the GLSM becomes strong, \( g_{QM} \to \infty \), the original quantum mechanics is restored. What is important is that we can compute an index

\[
\tilde{Z}_k = \text{Tr}_{\tilde{H}_k} (-1)^F e^{i\beta H} \epsilon^{i\beta (\epsilon_1 J_1 + \epsilon_2 J_2)} e^{i\beta a_i \Pi^j} e^{i\beta u \cdot K} \tag{2.5}
\]

which is parallel to \( Z_k^{(5d)} \), where \( \tilde{H}_k \) is the Hilbert space of this GLSM, which may be different\(^8\) from the \( H_k \) in (2.1). We regard the theory as a circular reduction of a 2d GLSM on a torus \( T^2 \) and connect the index (2.5) to the elliptic genus [22], which is a 2d index given by an integration of a meromorphic top form whose integration cycle is explicitly determined.

In fact, the authors of [24] performed the above program. For the 4d Nekrasov partition functions, this work plays the role of rewriting the naive integrals into ones whose integrands are the same as given by a naive application of the localization method and whose integration cycles are expressed by clearer forms. More precisely, it was found that performing the integrals with respect to these cycles is equivalent to applying the Jeffrey–Kirwan residue operator [25] to their integrands.

As a result, we now have a UV-completed version of the Nekrasov partition function by use of the GLSMs, and then we can rewrite them into the clearer forms

\[
Z = \int d\phi_1 \cdots d\phi_n Z \Rightarrow \tilde{Z} = \sum_{\phi_s} \text{JK-Res}_{\eta, \phi_s} Z, \tag{2.6}
\]

where the sum is taken over all the poles \( \phi_s \) of the integrand \( Z \), and the operator JK-Res\(_{\eta, \phi_s} \) is the Jeffrey–Kirwan residue with respect to a vector \( \eta \in \mathbb{R}^n \) around the pole \( \phi_s \). In the following, we explain the details of the operator.

2.2. Jeffrey–Kirwan residue

The JK-residue is an operator which maps a rational function to a value, the “residue” of the function at a point. Here, following [28,29], we introduce some minimum essentials of the operator in order to apply it to Nekrasov partition functions.\(^9\)

\(^8\) We have two indices, (2.1) and (2.5). The difference may come from the additional vector multiplet in the GLSM. This multiplet does not have dynamical degrees in the strong coupling limit \( g_{QM} \to \infty \) and then one can say that the difference occurs from the UV region. Here we can choose the corresponding quantum mechanics of D0-branes as the UV-completed one.

\(^9\) In this paper, however, we do not explain why the JK-residue gives the correct integration cycle. See [22–24].
2.2.1. Notation and definition of the Jeffrey–Kirwan residue

Here we introduce some notations and then define the JK-residue of rational functions of $n$ variables.

Let $Q_s \subset \mathbb{R}^n$ be a finite subset of nonzero elements and fix a point $\phi_s = (\phi_{sj})_{1 \leq j \leq n} \in \mathbb{C}^n$. We denote by $\hat{F}_{\phi_s}$ the set of formal power series of $n$ variables $\phi_j - \phi_{sj} \ (1 \leq j \leq n)$ and by

$$\hat{R}_{Q_s, \phi_s} := \text{span}_C \left\{ \frac{f}{\prod_{Q \in Q_s} (Q \cdot (\phi - \phi_s))^m} \mid f \in \hat{F}_{\phi_s}, m \in \mathbb{N} \right\}$$

the ring generated over $\hat{F}_{\phi_s}$ by inverting the linear functions $Q \cdot (\phi - \phi_s) \ (Q \in Q_s)$. This is graded by the degree at $\phi_s$ and then we denote its degree $-n$ part by $\hat{R}_{Q_s, \phi_s}[-n]$.

Let $\kappa$ be a subset of $Q_s$. The subset $\kappa$ is called a basis of $Q_s$ if $\kappa$ forms a basis of $\mathbb{R}^n$. For a basis $\sigma$ of $Q_s$, set

$$f_\sigma := \frac{1}{\prod_{Q \in \sigma} Q \cdot (\phi - \phi_s)}.$$  

We call such a fraction $f_\sigma$ basic. Then we denote by $S_{Q_s, \phi_s}$ the linear span of the $f_\sigma$ where $\sigma$ ranges over all the bases of $Q_s$. Clearly, $S_{Q_s, \phi_s} \subset \hat{R}_{Q_s, \phi_s}[-n]$.

Also, we denote by $NS_{Q_s, \phi_s}$ the linear span of degree $-n$ rational functions in the form

$$\psi \prod_{Q \in \kappa} (Q \cdot (\phi - \phi_s))^mQ$$

where $\psi$ is a polynomial function, $\kappa$ does not contain any bases of $Q_s$, and the $n_Q$ are non-negative integers.

It is proved that one can decompose $\hat{R}_{Q_s, \phi_s}[-n]$ into these two spaces:

**Proposition ([28])** We have a direct sum decomposition

$$\hat{R}_{Q_s, \phi_s}[-n] = S_{Q_s, \phi_s} \oplus NS_{Q_s, \phi_s}.$$  

From now on, we restrict ourselves to the case when $Q_s$ satisfies the following projectivity condition.

**Definition** We call $Q_s$ projective if there is a vector $\delta \in \mathbb{R}^n$ which has positive inner products with any elements of $Q_s$.

We call a vector $\eta \in \mathbb{R}^n$ generic if $\eta \notin \text{span}_\mathbb{R}\{Q_1, \ldots, Q_{n-1}\}$ for any $n - 1$ elements $Q_j \ (1 \leq j \leq n - 1)$ of $Q_s$.

Fix a generic vector $\eta$; we define the Jeffrey–Kirwan residue of a basic fraction $f_\sigma$ for the projective $Q_s$ by

$$\text{JK-Res}_{\eta, \phi_s} (f_\sigma d\phi_1 \wedge \cdots \wedge d\phi_n) := \begin{cases} |\det(Q_1 \cdot e_j)|^{-1} \quad &\eta \in \text{Cone}(Q_1, \ldots, Q_n) \\ 0 &\text{otherwise}, \end{cases}$$

where $\{e_j\}_{1 \leq j \leq n}$ is the canonical basis of $\mathbb{R}^n$, $\sigma = \{Q_1, \ldots, Q_n\}$, and

$$\text{Cone}(\sigma) = \text{Cone}(Q_1, \ldots, Q_n) := \left\{ \sum_{j=1}^n a_j Q_j \in \mathbb{R}^n \mid a_1, \ldots, a_n > 0 \right\}.$$
PROPOSITION (28) Given that \( Q^* \) is projective, the definition in (2.11) gives a well-defined linear functional \( \text{JK-Res}_{\eta, \phi^*} \) on \( S_{Q^* \cdot \phi^*} \).\(^{10}\)

Remark Note that there are linear relations among the basic fractions and then the above proposition claims that the JK-residue of each element in \( S_{Q^* \cdot \phi^*} \) does not depend on how we decompose it into some basic fractions.

DEFINITION (The Jeffrey–Kirwan residue) For a projective \( Q^* \) and a generic vector \( \eta \), the Jeffrey–Kirwan residue

\[
\text{JK-Res}_{\eta, \phi^*} : \hat{R}_{Q^* \cdot \phi^*} \to \mathbb{C}
\]

is defined to be the composite of

\[
\hat{R}_{Q^* \cdot \phi^*} \xrightarrow{\text{Project}} \hat{R}_{Q^* \cdot \phi^*}[-n] \xrightarrow{(2.10)} S_{Q^* \cdot \phi^*} \xrightarrow{(2.11)} \mathbb{C}.
\]

Remark The union of hyperplanes of non-generic points divides the whole space \( \mathbb{R}^n \) into connected components of generic points. Each connected component is often called a chamber. Note that two generic points in the same chamber give the same JK-residue. In other words, a chamber defines a JK-residue operator.

2.2.2. A setup to apply the JK-residue to the Nekrasov partition function

Now we want to apply the JK-residue to the Nekrasov partition function \( Z \). We denote its integrand by \( Z \), which is a rational function of \( n \) variables \( \phi_1, \ldots, \phi_n \), and its denominator is factorized into a product of degree-one polynomials.

Each factor in the denominator describes an affine hyperplane \( H \) in \( \mathbb{C}^n \). We can choose that the coefficient vector \( Q \), which defines \( H = \{ \phi \in \mathbb{C}^n | Q \cdot \phi + \text{const} = 0 \} \), is in \( \mathbb{R}^n \). We fix the vector \( Q \) for each hyperplane \( H \) and define \( \tilde{Q} \) to be the set of all such vectors.

DEFINITION (\( \tilde{Q} \) for Nekrasov partition functions) We fix the vector for each factor in the denominators of the pure SYM’s Nekrasov partition functions as follows:

\[
\pm \phi_j \pm a_l - \varepsilon_{+}, \pm \phi_j - \varepsilon_{1,2,+}, \pm \phi_j - \frac{\varepsilon_{1,2}}{2} \Rightarrow Q = \pm e_j \\
\pm \phi_l \pm \phi_j - \varepsilon_{1,2} \Rightarrow \tilde{Q} = \pm e_i \pm e_j.
\]

Then we have two sets of vectors:

\[
\tilde{Q}^A = \{ \pm e_j | j = 1, \ldots, n \} \cup \{ \pm (e_i - e_j) | 1 \leq i < j \leq n \}
\]

for \( G = U(N) \) and

\[
\tilde{Q}^{BCD} = \{ \pm e_j | j = 1, \ldots, n \} \cup \{ \pm (e_i \pm e_j) | 1 \leq i < j \leq n \}
\]

for \( G = SO(N), Sp(N) \), where \( \{ e_j | 1 \leq j \leq n \} \) is the canonical basis of \( \mathbb{R}^n \).

Remark The above choices of signs reflect that the physically motivated contour of each \( \phi_j \) should separate \( +\varepsilon_{1,2} \) and \( -\varepsilon_{1,2} \).

\(^{10}\) We define the JK-residue of a rational function by that of the meromorphic top form obtained by multiplying a fixed top form \( d\phi_1 \wedge \cdots \wedge d\phi_n \) to the function.
Now we take a point \( \phi_s \in \mathbb{C}^n \). Then we denote by \( \mathbf{Q}_s = \mathbf{Q}_s(\phi_s) \) the subset of \( \hat{\mathbf{Q}} \) that consists of all the coefficient vectors which come from the hyperplanes that contain \( \phi_s \). The Taylor expansion of the factors except those in the denominator that vanish at \( \phi_s \) gives an element of \( \hat{\mathbf{R}}_{\mathbf{Q}_s, \phi_s} \).

We can see from (2.14) that the JK-residue at \( \phi_s \) vanishes if \( \mathbf{Q}_s \) does not contain any basis. Then there are only a finite number of points where the JK-residue of \( Z \) does not vanish.

Also, for Nekrasov partition functions, the projectivity condition holds for each \( \phi_s \). The \( n \) components \( \phi_j \) of \( \phi_s \) are partially ordered by their coefficients on \( \varepsilon_1 \) and \( \varepsilon_2 \). Thanks to the minus on every \( \varepsilon_{1,2,+} \) in (2.15), this order gives a vector \( \delta \) such that \( \delta \cdot Q > 0 \) for any \( Q \in \mathbf{Q}_s \).

Then, provided a generic vector \( \eta \) with respect to the \( \hat{\mathbf{Q}} \), we get a finite sum of the JK-residues

\[
Z_\eta \equiv \sum_{\phi_s} \text{JK-Res}_{\eta, \phi_s} Z
\]

by regarding the integrand \( Z \) as an element of \( \hat{\mathbf{R}}_{\mathbf{Q}_s, \phi_s} \) for each point \( \phi_s \).

**Remark** We should choose the \( \eta \) physically. In this regard, the authors of [22–24] identified the vector as follows:

\[
G = U(N) \quad \Rightarrow \quad \eta = (1, 1, \ldots, 1) \\
G = SO(N), Sp(N) \quad \Rightarrow \quad \eta \text{ is arbitrary.}
\]

In the following, for easier calculations, we will choose \( \eta = (1, \alpha, \ldots, \alpha^{n-1}) \in \mathbb{R}^n \) with a large \( \alpha \) when we tackle with the \( BCD \)-type Nekrasov partition functions.

### 2.2.3. The sum of Jeffrey–Kirwan residues over a Weyl orbit

Before going to explicit calculations, it may be useful to consider a sum of JK-residues over a Weyl orbit \( \left[ \hat{\phi}_s \right] \) of a pole \( \phi_s \).

Let \( \hat{G} \) be a simple Lie group with rank \( n \) and \( \hat{\mathbf{G}} \) = Lie(\( \hat{G} \)). Set \( (\phi_1, \ldots, \phi_n) \) to a linear coordinate of the Cartan subalgebra of the complexified Lie algebra \( \hat{\mathbf{g}}_{\mathbb{C}} \). We denote the Weyl group of \( \hat{\mathbf{g}} \) by \( W \subset O(n) \). Given a Weyl symmetric rational function \( Z = Z(\phi_1, \ldots, \phi_n) \), let us consider the sum of all the JK-residues

\[
Z_\eta \equiv \sum_{\phi_s} \text{JK-Res}_{\eta, \phi_s} Z.
\]

Here we assume that the denominator of \( Z \) is completely factorized into distinct affine hyperplanes and the JK-residues are nonzero only at finite \( \phi_s \).s. We also assume that the \( \mathbf{Q}_s \) for each pole \( \phi_s \) is contained in \( \mathbb{R}^n \) and is projective. We take the vector \( \eta \) to be at a regular point with respect to any \( \mathbf{Q}_s \).

Thanks to the Weyl symmetry of \( Z \), we can relate JK-residue operators in the same Weyl orbit as follows:

**PROPOSITION** For \( g \in W \), we have \( \text{JK-Res}_{g, \eta, \phi_s} Z = \text{JK-Res}_{\eta, \phi_s} Z \).

**Proof** The action of an element \( g \in W \) gives a map from \( \hat{\mathbf{R}}_{\mathbf{Q}_s, \phi_s} [\!-n\!] \rightarrow \hat{\mathbf{R}}_{\mathbf{Q}_s, g \cdot \phi_s} [\!-n\!] \), which preserves their grades. More precisely, for a vector \( P \in \mathbb{R}^n \) and \( g \in W \), we have

\[
P \cdot (g^{-1} \cdot \phi - \phi_s) = (g \cdot P) \cdot (\phi - g \cdot \phi_s).
\]

This action also conserves the decomposition \( \hat{\mathbf{R}}_{\mathbf{Q}_s} [\!-n\!] = \mathbf{S}_{\mathbf{Q}_s} \oplus N \mathbf{S}_{\mathbf{Q}_s} \) and maps a basic fraction \( f_\sigma \in \mathbf{S}_{\mathbf{Q}_s, \phi_s} \) to another basic fraction \( f_{g \cdot \sigma} \in \mathbf{S}_{\mathbf{Q}_s, g \cdot \phi_s} \), where \( g \cdot \sigma := \{ g \cdot Q \mid Q \in \sigma \} \) forms a basis of \( \mathbf{Q}_s(g \cdot \phi_s) \).

8/33
Now let us consider the map \( \hat{R}_{Q,\phi_s} \to S_{Q,\phi_s} \) in the part of (2.14) at \( \phi_s \). Thanks to the Weyl symmetry of \( Z \), the above discussion shows that if we have a linear combination \( \sum_{\sigma} c_{\sigma}(\phi_s) f_{\sigma} \in S_{Q,\phi_s} \) of basic fractions as the image of \( Z \) by the map at \( \phi_s \), then we also have \( \sum_{\sigma} c_{\sigma}(\phi_s) f_{g,\sigma} \in S_{Q,g,\phi_s} \) as the one at the position \( g \cdot \phi_s \).

For the projectivity of \( Q, \) the JK-residue of the \( \sum_{\sigma} c_{\sigma}(\phi_s) f_{\sigma} \) at \( \phi_s \) is

\[
\text{JK-Res}_{\eta,\phi_s} \left( \sum_{\sigma} c_{\sigma}(\phi_s) f_{\sigma} \right) = \sum_{\sigma} \frac{c_{\sigma}(\phi_s)}{\det(Q_i^{\sigma} \cdot e_j)} I_{\text{Cone}(\sigma)}(\eta),
\]

where we write \( \sigma = \{Q_1^\sigma, \ldots, Q_n^\sigma\} \) and \( I_A \) is the characteristic function for a subset \( A \subset \mathbb{R}^n \). On the other hand, we have

\[
\text{JK-Res}_{g,\eta,\phi_s} \left( \sum_{\sigma} c_{\sigma}(\phi_s) f_{g,\sigma} \right) = \sum_{\sigma} \frac{c_{\sigma}(\phi_s)}{\det(Q_i^{g,\sigma} \cdot e_j)} I_{\text{Cone}(g,\sigma)}(g \cdot \eta).
\]

Clearly, \( I_{\text{Cone}(g,\sigma)}(g \cdot \eta) = I_{\text{Cone}(\sigma)}(\eta) \). Also we have \( \det(Q_i^{g,\sigma} \cdot e_j) = \det(Q_i^{\sigma} \cdot e_j) \) since \( W \subseteq O(n) \). Then we conclude that 
\[
\text{JK-Res}_{g,\eta,\phi_s} Z = \text{JK-Res}_{\eta,\phi_s} Z.
\]

Next we consider a sum of JK-residues over the Weyl orbit of \( \phi_s \) with respect to a fixed chamber \( \eta \). From (2.23), we have

\[
\frac{1}{C_{[\phi_s]}} \sum_{g \in W} \text{JK-Res}_{g,\eta,\phi_s} Z = \frac{1}{C_{[\phi_s]}} \sum_{\sigma} c_{\sigma}(\phi_s) \sum_{g \in W} I_{\text{Cone}(g,\sigma)}(\eta),
\]

where \( Z \in \hat{R}_{Q,\phi_s} \mapsto \sum_{\sigma} c_{\sigma}(\phi_s) f_{\sigma} \in S_{Q,\phi_s} \) and \( C_{[\phi_s]} \) is the order of the stabilizer subgroup at \( \phi_s \). In particular, \( \eta \) only appears in the factor \( A_{\sigma,\eta} = \sum_{g \in W} I_{\text{Cone}(g,\sigma)}(\eta) \in \mathbb{N} \).

As a result, we have the following formula:\footnote{The sum \( \sum_{\sigma \in \mathcal{B}(Q_n)} \) is taken over all the bases of \( Q_n \). In other words the range depends on \( \phi_s \). So we denote by \( \mathcal{B}(Q_n) \subset Q^{B,C,D} \) the set of all the bases of \( Q_n \) and express the dependence explicitly.}

**PROPOSITION**  With the notations above, we have

\[
Z_\eta = \sum_{\phi_s} \text{JK-Res}_{\eta,\phi_s} Z = \sum_{[\phi_s]} \frac{1}{C_{[\phi_s]}} \sum_{\sigma \in \mathcal{B}(Q_n)} A_{\sigma,\eta} c_{\sigma}(\phi_s) \frac{1}{\det(Q_i^{\sigma} \cdot e_j)}.
\]

This formula will be used in the rest of this paper and we will concentrate on how to determine the number \( A_{\sigma,\eta} \).

**Remark** \( \eta \) only affects the number \( A_{\sigma,\eta} \). This structure implicitly appears in the case of the \( U(N) \) Nekrasov partition function. In this case, one encounters poles that can be described as an \( N \)-vector of Young tableaux. The corresponding vector of Young diagrams implies its orbit. When \( \hat{G} = U(n) \) and \( \eta = (1, 1, \ldots, 1) \in \mathbb{R}^n \), we have

\[
A_{\sigma,\eta} = \begin{cases} 
n! & \eta \in \text{Cone}(\sigma) \\ 0 & \text{otherwise} \end{cases}.
\]

In other words, any two poles in the same orbit contribute the result with the same value. So we usually see the famous formula of the \( U(N) \) instanton counting whose summation is taken over the whole vector of Young diagrams, rather than Young tableaux.
Going back to the $BCD$ Nekrasov partition functions, we want the formula of $A_{\sigma, \eta}$ which is an analogue of (2.26). For the case that one can extract only one basic fraction at the pole $\phi_s$, $A_{\sigma, \eta}$ was partly calculated and called the multiplicity factor in [20]. Unlike the unitary case, $A_{\sigma, \eta}$ varies for each orbit. In Appendix B, we comment more on the multiplicity from the viewpoint of the notion $A_{\sigma, \eta}$.

Thanks to previous works, especially to [24], we know we can take $\eta$ arbitrarily in these $BCD$ cases. In the next section, we will fix $\eta$ and give an algorithm that computes $A_{\sigma, \eta}$ with respect to this fixed vector.

**Remark** Because of the arbitrariness of the choice of $\eta$, we may take the average of $Z_\eta$ over all the chambers. Set $N_{\tilde{Q}}$ to be the number of chambers for $\tilde{Q}$, and we have

$$\frac{1}{N_{\tilde{Q}}} \sum_{\eta} Z_\eta = \sum_{[\phi_s]} \frac{1}{C_{[\phi_s]}} \sum_{\sigma \in B(\tilde{Q}_s)} \frac{c_\sigma(\phi_s)}{\det(\tilde{Q}_s^\sigma \cdot e_j)} \sum_{\eta} A_{\sigma, \eta} N_{\tilde{Q}}$$

$$= \sum_{[\phi_s]} |W| C_{[\phi_s]} \sum_{\sigma \in B(\tilde{Q}_s)} \frac{c_\sigma(\phi_s)}{\det(\tilde{Q}_s^\sigma \cdot e_j)} \text{Prop}(\text{Cone}(\sigma)), \quad (2.27)$$

where $\text{Prop}(\text{Cone}(\sigma))$ is the proportion of the cone in $\mathbb{R}^n$, which is no other than the ratio of the solid angle of the cone, or of the number of chambers in the cone.

3. Distinction rule

In the previous section, we encountered the factor

$$A_{\sigma, \eta} \equiv \sum_{g \in W} I_{\text{Cone}(g; \sigma)}(\eta) \in \mathbb{N}. \quad (3.1)$$

So it is important to judge whether $\eta \in \text{Cone}(\sigma)$ or not. In principle, one can do this by solving a system of linear equations. In this section, however, we give another way. We take a special vector as $\eta$, and then provide the main theorem of this section that claims a distinction rule to see whether $\eta \in \text{Cone}(\sigma)$ or not for a given cone of a basis $\sigma$ of $\tilde{Q}^{BCD}$. The rule will be expressed graphically, and we will see in the next section that this graphical notation matches the Weyl group actions on poles.

In this section, we first introduce some notation to clarify the discussions, and then we give the distinction rule.

3.1. Notation

Here we introduce some notation to make the discussions in this paper clearer. First, we introduce a graphical notation for the elements of $\tilde{Q}^{BCD}$.

For each element of $\tilde{Q}^{BCD}$, we write it as follows:

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$

$$\pm e_i \pm e_j \Rightarrow \bigcirc_i \pm \bigcirc_j.$$  

$$\pm e_i \Rightarrow \pm \bigcirc_i,$$
Following this notation, we define the graph of a subset $Q_s \subset \tilde{Q}^{BCD}$ which consists of $n$ vertices with numbers and $|Q_s|$ lines with signs on their ends.\footnote{This graph may be disconnected and have some isolated vertices.}

**Example** The graph of $Q = \{e_2, e_1 - e_2\}$ is $\begin{array}{c|c}
2 & 1 \\
\hline
\end{array}$.\begin{figure}[h]
\centering
\begin{tikzpicture}
\path (0,0) node[shape=circle,draw=black] (v1) {};
\path (1,0) node[shape=circle,draw=black] (v2) {};
\path (0.5,0) node[shape=circle,draw=black] (v3) {};
\path (v1) edge[<-,bend left] node[above] {$2$} (v2);
\path (v1) edge[<-,bend right] node[below] {$1$} (v3);
\end{tikzpicture}
\end{figure}

In the rest of this paper, we only consider such graphs, and then we call it a graph for short. We often abbreviate numbers or signs in a graph. Also, if $u$ is a vertex in a graph, we write by $m(u)$ the number assigned to $u$.

**Remark** Note that the Weyl group $S_n \ltimes \mathbb{Z}_2^n$ naturally acts on a graph. More precisely, $S_n$ permutes the assigned numbers for the vertices and $\mathbb{Z}_2^n$ flips the signs on the lines.

We also introduce some notions for tree graphs, connected graphs with no cycles. Note that we fix a vertex in a tree graph and call it the root of the tree.

For a given vertex $u$ in a tree graph, we say that a vertex $v$ is a descendant of the vertex $u$ when the path that connects $v$ and the root has the vertex $u$, and define $D(u)$ as the set of all the descendants of $u$. (Here we declare that $u$ is an element of $D(u)$.) Also, we define $M(u) \equiv \max_{v \in D(u)} m(v)$.

Finally, we introduce the concept of $\eta$-orientation, only for abbreviations.

**DEFINITION** For given a subset $\{Q_1, \ldots, Q_l\}$ of $\tilde{Q}^{BCD}$, we say that the set and its graph are $\eta$-oriented if the set satisfies $\eta \in \text{Cone}(Q_1, \ldots, Q_l)$.

### 3.2. The specific choice of chamber

In this paper, we choose

$$\eta = \left(1, \alpha, \alpha^2, \ldots, \alpha^{n-1}\right) \in \mathbb{R}^n,$$

where $\alpha > 0$ is a sufficiently large parameter. Before we consider JK-residues with respect to this vector, we should show the following lemma.

**LEMMA** Any set of $q(< n)$ vectors in $\tilde{Q}^{BCD}$ is not $\eta$-oriented. In other words, $\eta$ is generic.

In the following, we prove this lemma, which is a corollary of the following lemma.

**LEMMA** For any sequences $\left(p_j\right)_{1 \leq j \leq n}$ of integers such that $p_1 < p_2 < \cdots < p_n$, the vector

$$\eta(p_1, \ldots, p_n) \equiv \left(\alpha^{p_1}, \ldots, \alpha^{p_n}\right) \in \mathbb{R}^n$$

cannot be expressed as a linear combination of arbitrary $n - 1$ vectors in $\tilde{Q}^{BCD}$.

**Proof** We prove it by the mathematical induction for $n$. The $n = 1$ case holds because $\eta \neq 0$. Now we assume this claim holds for the $n < l$ cases and consider the $n = l$ case. If the claim does not
hold for this case, we have a sequence of integers $p_1 < \cdots < p_n$, vectors $Q_1, \ldots, Q_{n-1} \in \tilde{Q}^{BCD}$, and $a_1, \ldots, a_{n-1} \in \mathbb{R}$ such that
\[ a_1 Q_1 + \cdots + a_{n-1} Q_{n-1} = \eta(p_1, \ldots, p_n). \] (3.4)

Consider a projection $Q \in \tilde{Q}^{BCD} \mapsto Q' = Q - (e_1, Q)e_1 \in \mathbb{R}^{n-1}$. This projection gives a map to the one-dimensional lower $\tilde{Q}^{BCD} \sqcup \{0\} \subset \mathbb{R}^{n-1}$. So if $Q_1 = e_1$, this projection gives
\[ a_2 Q'_2 + \cdots + a_{n-1} Q'_{n-1} = \eta(p_2, p_3, \ldots, p_n), \] (3.5)
which contradicts the assumption. Therefore $Q_1, \ldots, Q_{n-1}$ are of the form $\pm(e_i \pm e_j)$. Moreover, if $Q_1$ and $Q_2$ are of the form $\pm(e_1 \pm e_2)$, we have a contradiction similarly by dropping $e_1$ and $e_2$.

Similarly, if $q(<k)$ vectors $Q_{j_1}, \ldots, Q_{j_q}$ are spanned by $e_1, \ldots, e_q$, we have a contradiction.

The above result is translated into the fact that this graph with $k$ vertices and $k-1$ lines contains no loops:

\[ \text{\includegraphics[width=0.5\textwidth]{tree_diagram.png}} \] (3.6)

In other words, the graph is made of trees.\(^\dagger\)

Equation (1.1) gives a system of $k$ linear equations. We start to solve this from the leaves of the graph to a fixed root. Finally, we have the following single relation:
\[ \sum_{i=1}^{n} \pm \alpha p_i = 0 \] (3.7)
with appropriate signs. But $\alpha$ is large enough and then $\sum_{i=1}^{n} \pm \alpha p_i \neq 0$, which is a contradiction.

So the claim holds for the $n = l$ case, and then for any $n$.\(\square\)

### 3.3. Distinction rule

To evaluate JK-residues, it is important to distinguish whether a basis $\sigma = (Q_1, \ldots, Q_n)$ of $\tilde{Q}^{BCD}$ is $\eta$-oriented. So here we give a distinction rule for a graph with the same number of lines and vertices and prove it. The resultant rule will then be summarized as a theorem and a corollary.

First we prove the following proposition that constrains the shape of an $\eta$-oriented graph.

**PROPOSITION** A graph with the same number of lines and vertices is $\eta$-oriented only if each of its connected components is expressed as a loop and trees associated to the vertices in the loop:

\[ \text{\includegraphics[width=0.5\textwidth]{tree_diagram.png}} \] (3.8)

where $\text{\includegraphics[width=0.1\textwidth]{tree.png}}$ means a tree graph.

\(^\dagger\)But we know for tree graphs that $\#(\text{connected component}) = \#(\text{vertex}) - \#(\text{line}) = 1$, so we should have a connected tree diagram.
Proof  Take an \( \eta \)-oriented graph with \( n \) lines \( Q_1, \ldots, Q_n \in \mathbb{Q}^{BCD} \) and \( n \) vertices. Then there is a solution of the system of \( n \) linear equations
\[
a_1 Q_1 + \cdots + a_n Q_n = \eta
\]
(3.9)
with \( a_1, \ldots, a_n > 0 \).

If one connected component of the graph has more lines than vertices, we drop all vertices and lines in this component and get a subsystem of linear equations for the remaining graph with more vertices than lines. But the previous discussion shows that this system and then (3.9) have no solution. Therefore, each connected component of the \( \eta \)-oriented graph has the same number of lines as vertices, and then has just one loop.

\[\blacksquare\]

Remark  Dropping the lines which make the loop, we get tree subgraphs. For each tree subgraph, we assign the root of the tree to the unique vertex that is originally in the loop.

What remains to get a distinction rule is to assign numbers and signs to the graph. To get intuition for the rule, we consider several examples below.

Example (1. Straight tree)  Here we consider the \( \eta \)-oriented graph
\[
\begin{array}{c}
\bigcirc & \bigcirc & \bigcirc & \cdots & \bigcirc \\
Q_1 & u_1 & Q_2 & u_2 & Q_3 & \cdots & Q_n & u_n \\
p_1 & q_1 & p_2 & q_2 & \cdots & p_n & q_n \\
1 & 2 & 3 & \cdots & n
\end{array}
\]
(3.10)
of \( n \) vertices \( u_1, \ldots, u_n \) and \( n \) lines \( Q_1, \ldots, Q_n \), where \( p_1, \ldots, p_n \) and \( q_1, \ldots, q_{n-1} \) are \( \pm 1 \).

The distinction rule for this graph (3.10) is as follows.

**Lemma**  The graph (3.10) is \( \eta \)-oriented if and only if \( p_n = +1 \) and
\[
(p_i, q_i) = \begin{cases} (+, -), (-, +) & M(u_i) > m(u_i) \\ (+, \pm) & M(u_i) = m(u_i) \end{cases}
\]
(3.11)
for each \( i < n \).

**Proof**  Let us consider the \( u_n \). We start to solve the system of linear equations (3.9) from this vertex and we have
\[
p_n a_n = (\eta, e_{m(u_n)}) = \alpha^{m(u_n)-1}.
\]
(3.12)
Then we get \( p_n = +1 \) and \( a_n = \alpha^{m(u_n)-1} > 0 \).

Next we consider the vertex \( u_{n-1} \) and we have
\[
p_{n-1} a_{n-1} = \alpha^{m(u_{n-1})-1} - q_n a_n = \alpha^{m(u_{n-1})-1} - q_n \alpha^{m(u_n)-1}.
\]
(3.13)
Since \( \alpha \) is large enough, we get
\[
(p_{n-1}, q_{n-1}; a_{n-1}) = \begin{cases} (+, -; \alpha^{m(u_{n-1})-1} + \alpha^{m(u_n)-1}), (-, +; -\alpha^{m(u_{n-1})-1} + \alpha^{m(u_n)-1}) & m(u_n) > m(u_{n-1}) \\ (+, \pm; \alpha^{m(u_{n-1})-1} \mp \alpha^{m(u_n)-1}) & m(u_n) < m(u_{n-1}) \end{cases}
\]
(3.14)
In particular, \( a_{n-1} \) is of the order \( \alpha^{M(u_{n-1})} \).
Similarly, for a general vertex $u_i$, we have

$$p_i a_i + q_i a_{i+1} = \alpha^{m(u_i) - 1}. \quad (3.15)$$

Note that $a_{i+1}$ is as large as $\alpha^{M(u_{i+1})}$. Then we get

$$(p_i, q_i) = \begin{cases} (+, -), (-, +) & M(u_i) > m(u_i) \\ (+, \pm) & M(u_i) = m(u_i) \end{cases}, \quad (3.16)$$

and $a_i$ is as large as $\alpha^{M(u_i)}$.

Note that one can see whether the signs are allowed for the $\eta$-oriented graph only by considering $M(u)$ and $m(u)$.

**Example (2. Loop)** Next we consider a loop graph,

$$
\begin{array}{c}
Q_{n-1} \\

\vdots \\

Q_n \\

\end{array}
\begin{array}{c}
p_1 \\
q_1 \\
\vdots \\
p_n \\
q_n \\
\end{array}
\begin{array}{c}
u_n \\
\text{...} \\
u_1 \\
\text{...} \\
u_2 \\
\end{array}
\begin{array}{c}
Q_1 \\
Q_2 \\
\end{array}
\begin{array}{c}
p_2 \\
q_2 \\
\end{array}
$$

with $n$ lines and $n$ vertices. We may assume $m(u_1) = n > m(u_i)$ for each $i \geq 2$.

**Lemma** The graph (3.17) is $\eta$-oriented if and only if it is of the form

$$
\begin{array}{c}
-p_n \\
\vdots \\
-p_1 \\
p_1 \\
p_2 \\
\end{array}
\begin{array}{c}
-p_2 \\
p_2 \\
\end{array}
\begin{array}{c}
\vdots \\
\text{...} \\
\text{...} \\
\text{...} \\
\text{...} \\
\text{...} \\
\end{array}
$$

where $p_i = \pm 1$ for each $2 \leq i \leq n$.

**Proof** Since $a_1, a_n$ in (3.9) are positive, either $p_1$ or $q_1$ is also positive. We may assume that $p_1 = +1$ and $a_1$ is of the order $\alpha^{k-1}$ at least. If not, the system (3.9) cannot be satisfied for $a_1, a_n > 0$.

Next we focus on the vertex $u_2$ and see that, in order to satisfy $a_1 q_2 + a_2 p_2 \leq \alpha^{n-2}$, $p_2$ and $q_2$ have signs opposite to each other and $a_2$ is as large as $a_1$.

Inductively, we can see that $p_i$ and $q_i$ have signs opposite to each other for each $1 < i \leq n$. Since the $n$ vectors $Q_1, \ldots, Q_n$ become a basis of $\mathbb{R}^n$,

$$0 \neq \left| \det(Q_1, \ldots, Q_n) \right| = \prod_{i=1}^{n} p_i + (-1)^{n-1} \prod_{i=1}^{n} q_i = \left| 1 + p_1 q_1 \right| \quad (3.19)$$

must be satisfied. This determines $q_1 = +1$. 

14/33
Conversely, if such assignments are given, the system (3.9) gives
\[ a_i = p_i \alpha^{m(u_i)-1} + a_{i-1} (i = 2, \ldots, n), \]
and then
\[ a_1 = \alpha^{n-1} - a_n = \alpha^{n-1} - a_1 - \sum_{i=2}^{n} p_i \alpha^{m(u_i)-1}. \]

So the system (3.9) has a solution in the region where each \( a_i \) \((1 \leq i \leq n)\) is as large as \( \alpha^{n-1} \) and is necessarily positive.

**Distinction rule**

We are now ready to give a distinction rule for a general graph with the same number of lines and vertices. It is sufficient to give the rule for the graph (3.8).

For graph (3.8) with \( n \) lines and \( n \) vertices, the set \( V \) of all the vertices is classified into the classes
\[ V = \bigcup_{i=1}^{5} V_i, \]
where
\[ V_1 = \{ u \mid u \text{ is not in the loop and } m(v) = M(v) \} \]  
(3.22)
\[ V_2 = \{ u \mid u \text{ is not in the loop and } m(v) < M(v) \} \]  
(3.23)
\[ V_3 = \{ u \mid u \text{ is in the loop and } m(v) = M(v) = n \} \]  
(3.24)
\[ V_4 = \{ u \mid u \text{ is in the loop and } m(v) < M(v) = n \} \]  
(3.25)
\[ V_5 = \{ u \mid u \text{ is in the loop and } M(v) < n \}. \]  
(3.26)

For each vertex \( u \in V_1 \cup V_2 \), we denote by \( Q_u \) the line that connects \( u \) and the parent of \( u \), the unique vertex that links to \( u \) by a line and is not descendant to \( u \). Also, for each vertex \( u \in V_2 \cup V_4 \), we denote by \( T \) its descendant tree that has the vertex \( v \) with \( M(u) = m(v) \).

Using the above notation, the distinction rule for the graph (3.8) is as follows.

**Theorem (Distinction rule)** The graph (3.8) is \( \eta \)-oriented if and only if all the following conditions are satisfied.

(i) For each \( u \in V_1 \), the assignment is of the form

\[ Q_u u \begin{array}{c} + \end{array} \begin{array}{c} - \end{array} \begin{array}{c} \vdots \end{array} \begin{array}{c} \vdots \end{array} \begin{array}{c} \vdots \end{array} \]  
(3.27)

with double signs for the trees in any order, where each \( \bigcirc \) means a tree whose vertices are descendant to \( u \).

(ii) For each \( u \in V_2 \), the assignment is of the form

\[ Q_u u \begin{array}{c} + \end{array} \begin{array}{c} - \end{array} \begin{array}{c} \vdots \end{array} \begin{array}{c} \vdots \end{array} \begin{array}{c} \vdots \end{array} \]  
(3.28)

with double signs in any order and \( p_u = \pm 1 \).
(iii) For each vertex \( u \in V_3 \), the assignment is of the form

\[
\begin{align*}
\begin{array}{c}
+ \\
\sigma(-u) \\
+ \\
\end{array}
\end{align*}
\]

with double signs in any order, where the curves mean the lines in the loop.

(iv) For each vertex \( u \in V_4 \), the assignment is of the form

\[
\begin{align*}
\begin{array}{c}
p_u \\
\pm u \\
p_u \\
\end{array}
\end{align*}
\]

with double signs in any order and \( p_u = \pm 1 \).

(v) For each vertex \( u \in V_5 \), the assignment is of the form

\[
\begin{align*}
\begin{array}{c}
-p_u \\
\pm u \\
p_u \\
\end{array}
\end{align*}
\]

with double signs in any order and \( p_u = \pm 1 \).

**Proof**  (i), (ii) A similar discussion to Example 1 shows that the coefficient for the \( Q_u \) in (3.9) should be as large as \( a^{M(u)-1} \) and then gives the distinction rule for a vertex that is not in the loop.

(iii), (iv), (v) A similar discussion to Example 2 gives the distinction rule for a vertex in the loop.

**Corollary** A graph with the same number of lines and vertices is \( \eta \)-oriented if and only if each connected component of the graph is of the form (3.8) and satisfies the above distinction rule.

4. **Jeffrey–Kirwan residue of \( Sp(0) \) instantons**

In the previous section, we obtained the distinction rule for bases of \( \tilde{Q}^{BCD} \) with respect to the special vector \( \eta \). In this section, we will consider applications of the rule to the \( BCD \) Nekrasov partition functions. First, we introduce a tableau notation that represents Weyl orbits of the poles. This tableau specifies a class of graphs whose signs are relatively fixed, and then we use the distinction rule on the graph to calculate \( A_{\sigma, \eta} \). This notation resembles the famous Young diagrammatic notation for the poles of the \( U(N) \) Nekrasov partition function. For simplicity, we focus on the \( G = Sp(N) \) case, but one can do parallel discussions for \( G = SO(N) \).

Next, we will calculate JK-residues of “\( Sp(0) \)” instantons and see how our results work in the calculation. In Appendix A, we present a list of all the JK-residues of \( Sp(0) \) instantons up to \( k = 8 \).
As a result, we observe that
\[ Z_k^{Sp(0)} = \frac{(-1)^k}{2^k k! e_1^k e_2^k} \]  
for \( k \leq 8 \).

### 4.1. Box expressions for poles of \( Sp(N) \) instantons

For \( G = Sp(N) \), there are \( n \) variables to be integrated when we consider the Nekrasov partition function with instanton number \( k = 2n \) or \( k = 2n + 1 \). We want to know the JK-residue at \( \phi_\ast = (\phi_1_\ast, \ldots, \phi_n_\ast) \).

Following (2.15), one can obtain a graph of \( Q_\ast(\phi_\ast) \). If the graph may not contain an \( \eta \)-oriented subgraph with \( n \) lines,\(^{14}\) its JK-residue vanishes. A nontrivial pole should have an \( \eta \)-oriented retract.

This condition significantly restricts the position of \( \phi_\ast \) for the existence of the loop in (3.8). Each \( \phi_{\ast j} \) (\( 1 \leq j \leq n \)) is confined on \( 2N + 4 \) lattices,
\[
\begin{align*}
    &\pm a_l + (Z + \frac{1}{2}) \varepsilon_1 + (Z + \frac{1}{2}) \varepsilon_2 \quad (1 \leq l \leq N) \\
    &Z \varepsilon_1 + Z \varepsilon_2, (Z + \frac{1}{2}) \varepsilon_1 + Z \varepsilon_2, Z \varepsilon_1 + (Z + \frac{1}{2}) \varepsilon_2, (Z + \frac{1}{2}) \varepsilon_1 + (Z + \frac{1}{2}) \varepsilon_2.
\end{align*}
\]  

Mirroring by the overall \( Z_2 \) flip, we have the \( N + 4 \) classes of the lattices.

Now we rewrite such a pole \( \phi_\ast = (\phi_1_\ast, \ldots, \phi_n_\ast) \) by an \( (N + 4) \)-vector of tableaux, which has \( k \) boxes in total. First, put a box with number \( i \) at \( \phi_i_\ast \) and a box with character \( i' \) at \( -\phi_i_\ast \) for each \( 1 \leq i \leq n \). Then, if \( k \) is odd, put one additional box at 0 with number 0.

**Example** We write\(^{15}\) the pole of the 4-instanton at \( \phi_1_\ast = \frac{1}{2} \varepsilon_1 + \varepsilon_2, \phi_2_\ast = \frac{1}{2} \varepsilon_1 \) by
\[
\begin{array}{c}
  1' \\
  2' \\
  1 \\
\end{array}
\]  
and that of the 3-instanton at \( \phi_1_\ast = \varepsilon_1 \) by
\[
\begin{array}{c|c|c}
  1' & 0 & 1 \\
\end{array}
\]  

It is possible that multiple boxes are assigned at the same position. In this case, we should improve the expression in order to see the degeneracy. We express, for example, the pole of the 4-instanton at \( \phi_1_\ast = 0, \phi_2_\ast = \varepsilon_1 \) by
\[
\begin{array}{c|c|c}
  2' & 1.1' & 2 \\
\end{array}
\]  

and one can see that there are two boxes at 0.

Forgetting numbers and characters but not its degeneracy, one can get an \( (N + 4) \)-vector of diagrams for \( \phi_\ast \). Clearly, this vector\(^{16}\) represents a Weyl orbit \( [\phi_\ast] \) of poles.

---

\(^{14}\) A trivial example is a graph with \( |Q_\ast| < n \).

\(^{15}\) We omit null shapes in the other classes of lattices.

\(^{16}\) This object first appeared in [19] and was called a generalized Young diagram in [20].
Remark (The connection between box expressions and graphs) The notation merely gives another expression of poles. One can construct the graph from its box adjacency. For example,

\[
\begin{array}{c}
1' \\
\downarrow \\
2' \\
\downarrow \\
1
\end{array}
\rightarrow
\begin{array}{c}
\quad \\
\downarrow
\quad +
\end{array}
\rightarrow
\begin{array}{c}
\quad \\
\downarrow
\quad +
\downarrow
\quad +
\end{array}
\]  
(4.6)

Remark We can see from this box expression that some poles have vanishing JK-residues. For example, we consider the diagram for the case of the 4-instanton. Thanks to the vanishing factor \(\pm (\phi_1 \pm \phi_2) - \varepsilon\) in the numerator, this shape gives poles whose JK-residues are zero. For a general pole of the \(k = 2n, 2n + 1\)-instanton, from its diagrammatic expression we can see the number \(p\) of zero factors in the numerator of the integrand and the number \(q\) of those in the denominator. If \(p - q > -n\), the JK-residue of the pole vanishes.

4.2. \(Sp(0)\) instanton correction

From now on, we concentrate on the pure SYM’s instanton correction with gauge group “\(Sp(0)\),” or the JK-residues of the rational function

\[
Z^ {Sp(0)}_{k=2n+\chi} = \frac{1}{2^{2n-1}n!} \left( \frac{\varepsilon}{\varepsilon_1 \varepsilon_2} \right)^n \left( \frac{1}{2\varepsilon_1 \varepsilon_2} \right)^x \frac{1}{\prod_{j=1}^{n} (4\phi_j^2 - \varepsilon_1^2)(4\phi_j^2 - \varepsilon_2^2) \Delta(\varepsilon_1) \Delta(\varepsilon_2)},
\]  
(4.7)

where

\[
\Delta(x) = \left( \prod_{i<j} \left( (\phi_i - \phi_j)^2 - x^2 \right) \left( (\phi_i + \phi_j)^2 - x^2 \right) \right)^x \left( \prod_{j=1}^{n} (\phi_j^2 - x^2) \right). \quad (4.8)
\]

Note that the integrand \(Z^ {Sp(0)}_{k}\) is invariant under the Weyl group \(\Sigma_n \rtimes \mathbb{Z}_2^n\) action on \((\phi_1, \ldots, \phi_n)\). Then we have

\[
Z^ {Sp(0)}_{k} \equiv \sum_{\phi_*} \text{JK-Res}_{\eta, \phi_*} Z^ {Sp(0)}_{k} = \sum_{[\phi_*]} \frac{1}{C_{[\phi_*]}} \sum_{\sigma \in B(Q_\star)} \frac{A_{\sigma, \eta} c_{\sigma}(\phi_*)}{\det(Q_\star^j \cdot \varepsilon_j)},
\]  
(4.9)

where \(C_{[\phi_*]}\) is the order of the stabilizer group at \(\phi_*\) and

\[
A_{\sigma, \eta} = \sum_{g \in \Sigma_n \rtimes \mathbb{Z}_2^n} I_{\text{Con}(g, \sigma)}(\eta) \in \mathbb{N},
\]  
(4.10)

\[
Z^ {Sp(0)}_{k} \in \hat{R}_{Q_\star, \phi_*} \mapsto \sum_{\sigma \in B(Q_\star)} c_{\sigma}(\phi_*) f_{\sigma} \in S_{Q_\star, \phi_*}.
\]  
(4.11)

Here the map in the last is the part of the definition of the JK-residue (2.14).

A Weyl orbit \([\phi_*]\) that has nonvanishing JK-residue should be expressed as a 4-vector of diagrams with \(k\) boxes in total. Each component belongs to each of the four lattices

\[
Z_{\varepsilon_1} + Z_{\varepsilon_2}, \quad \left( Z + \frac{1}{2} \right) \varepsilon_1 + Z_{\varepsilon_2}, \quad Z_{\varepsilon_1} + \left( Z + \frac{1}{2} \right) \varepsilon_2, \quad \left( Z + \frac{1}{2} \right) \varepsilon_1 + \left( Z + \frac{1}{2} \right) \varepsilon_2.
\]  
(4.12)
We do the extraction (4.11) for each nontrivial orbit and calculate the $A_{\sigma,\eta}$ for each basis $\sigma$ with $c_\sigma(\phi_s) \neq 0$ by applying the distinction rule to the set. Here we set $\eta = (1, \alpha, \ldots, \alpha^{n-1})$ for a fixed sufficiently large $\alpha$ and then the distinction rule determines the $A_{\sigma,\eta}$.

Also, we can determine the factor $|\det(Q^\sigma \cdot e_j)|$. For a given class of subgraphs, each connected component contributes to this factor by 1 if its loop is of the form $\bigcirc \bigcirc$, or by 2 otherwise.

What remains to determine $Z_{k,\eta}^{Sp(0)}$ is $c_\sigma(\phi_s)$, the decomposition coefficients of $Z_{k,\eta}^{Sp(0)}$ into the basic fractions.

**Example (An explicit JK-residue calculation)** Here we give an example of a JK-residue calculation in order to see the algorithm more clearly.

Let us consider the pole of $Z_{k,\eta}^{Sp(0)}$ at $\phi_{s1} = \phi_{s2} = \frac{1}{2}\varepsilon_1, \phi_{s3} = \frac{3}{2}\varepsilon_1$. Then its orbit is expressed by $\bigcirc \bigcirc \bigcirc$, where each gray box represents two boxes. We see $C_{[\phi_s]} = 2$ from its overlap.

From the numerator, we count $p = 2$ for $\phi_{s1} - \phi_{s2} = 0$. On the other hand, from the denominator, we count $q = 5$ from $\phi_{s1} - \frac{1}{2}\varepsilon_1 = \frac{1}{2}\varepsilon_1 = \phi_{s1} + \phi_{s2} - \varepsilon_1 = 0$ and $\phi_{s3} - \phi_{s1} - \varepsilon_1 = \phi_{s3} - \phi_{s2} - \varepsilon_1 = 0$. So this orbit may have non-zero JK-residue for $2 - 5 = -3 = -n$. In particular, the total degree of zero factors at $\phi_s$ is $-3$, and then we expand the remainder of the integrand at order 0, which gives

$$c = -\frac{(2\varepsilon_1 + \varepsilon_2)(3\varepsilon_1 + \varepsilon_2)}{27648\varepsilon_1^6(\varepsilon_1 - \varepsilon_2)^3(2\varepsilon_1 - \varepsilon_2)^2(3\varepsilon_1 - \varepsilon_2)\varepsilon_2^2}. \quad (4.13)$$

The corresponding class of graphs for the orbit $[\phi_s]$ is

$$\begin{array}{c}
\bigcirc \\
\bigcirc \\
\bigcirc
\end{array}$$

where $p_1, p_2,$ and $p_3$ are $\pm 1$. The Weyl group action ends up flipping these signs and permuting the assigned numbers.

Note that the zero factors in the numerator become

$$(\phi_1 - \phi_2)^2 = -\left[ (\phi_1 - \frac{\varepsilon_1}{2}) - (\phi_2 - \frac{\varepsilon_1}{2}) \right] \left[ (\phi_3 - \phi_1 - \varepsilon_1) - (\phi_3 - \phi_2 - \varepsilon_1) \right]. \quad (4.15)$$

then we have a decomposition of the zero factors into some basic fractions

$$-f_{\sigma_1} + f_{\sigma_2} + f_{\sigma_3} - f_{\sigma_4}, \quad (4.16)$$

\[19/33\]
where

\[
\begin{align*}
\sigma_1 &= -p_1 - p_2 p_3 p_2 - p_1 p_3 p_2 \\
\sigma_2 &= -p_1 - p_2 p_3 p_2 - p_1 p_3 p_2 \\
\sigma_3 &= -p_1 - p_2 p_3 p_2 - p_1 p_3 p_2 \\
\sigma_4 &= -p_1 - p_2 p_3 p_2 - p_1 p_3 p_2 
\end{align*}
\]

(4.17)

Using the distinction rule, we have

\[
A_{\sigma_1, \eta} = A_{\sigma_4, \eta} = 6, \quad A_{\sigma_2, \eta} = A_{\sigma_3, \eta} = 3.
\]

(4.18)

Thus we get the sum of the JK-residues over the orbit \([\phi_*]:\)

\[
\sum_{\psi_* \in [\phi_*]} \text{JK-Res}_{\eta, \psi_*} Z_{Sp}^{S_{\phi}(0)} = \frac{c}{2} (-6 + 3 + 3 - 6) \]

\[
= \frac{(2 \varepsilon_1 + \varepsilon_2)(3 \varepsilon_1 + \varepsilon_2)}{9216 \varepsilon^6_1 (\varepsilon_1 - \varepsilon_2)^3 (2 \varepsilon_1 - \varepsilon_2)^2 (3 \varepsilon_1 - \varepsilon_2) \varepsilon_2^2}.
\]

(4.19)

Remark In general, the calculation becomes easier if one considers a pole \(\phi_* \in \mathbb{C}^n\) where the integrand has no terms below degree \(-n\) at \(\phi_*\), because one needs only the zeroth term of the Taylor series of the nonzero factors.

We can do similar calculations for other Weyl orbits. We give a list of the explicit residues for \(k \leq 8\) in Appendix A. Finally, we observed the following property:

**Observation** We have

\[
Z_{Sp}^{S_{\phi}(0)} = \frac{(-1)^k}{2^k k! \varepsilon_1^k \varepsilon_2^k},
\]

(4.20)

at least for \(k \leq 8\).

This observation seems to be generalized for any \(k\) and looks to be an analogue of the combinational formula \(Z_k^{U(1)} = (k! \varepsilon_1^k \varepsilon_2^k)^{-1}\).

5. Discussions

In this paper, we have made an algorithm to calculate the \(BCD\)-type Nekrasov partition functions more easily and then observed (4.20) for the \(Sp(0)\) case for small instanton numbers. One can determine the residue of a Weyl orbit of poles, or a diagram without considering awkward cancellations of iterated residues, but with the distinction rule we have proposed. We hope that this algorithm will help readers to calculate some multi-contour integrals. However, we have calculated residues mainly
by substituting positions of poles for the nonzero factors in the integrand. We have calculated the JK-
residues of 106 Weyl orbits for the $Sp(0)$ 8-instanton correction and found that 104 orbits contribute
to the correction. For larger instanton numbers, one should encounter more orbits. Then it is desirable
to express them only by some manipulations of box diagrams, like the formula with Young diagrams
for the $U(N)$ case. Also, we have observed the two nontrivial orbits and whose joint
residues vanish. We do not confirm the set of all the orbits with nonzero joint residues. One way to
tackle this problem is to construct a recursion relation among the fixed points, or to understand how
the residues change when one adds boxes to the poles. In this regard, our distinction rule may play
a role in calculating the ratio of two $A_{\sigma,\eta}$ through graphical considerations. However, the relation
is not clear because one sometimes needs to differentiate the nonzero part of the integrand at a pole to
evaluate its JK-residue. For example, we did such a differentiation when we evaluated the JK-residue
at the orbit. This differentiation makes it difficult to rephrase the recursion relation in terms of
box manipulations.

This simple form of the sum for the $U(1)$ Nekrasov partition function can be understood from the
perspective of Hilbert schemes of points on $\mathbb{C}^2$ [4,5]. Roughly, this property is described as

$$\int_{\mathbb{C}^2/\mathbb{S}_k} 1 = \frac{1}{k!\delta_1^k\delta_2^k}. \tag{5.1}$$

Moreover, the residue formula for the $U(1)$ case can be expressed as the combinational formula of
Jack polynomials. Maybe there is a similar background behind the $Sp(0)$ case. Is there an analog $X_k$
which gives

$$\int_{X_k} 1 = \frac{(-1)^k}{2^k k!\delta_1^k\delta_2^k} \tag{5.2}$$

and corresponding orthogonal polynomials? If one can show it explicitly, then it will enable the explo-
ration of how outer automorphisms of Lie algebras act on instantons with different gauge groups,
which may lead to a deeper understanding of gauge theories with exceptional gauge groups because
any exceptional Lie algebras relate to some classical Lie algebras through such automorphisms.

Physically, the $U(N)$ Nekrasov partition function can be realized from a D0–D4 system. Similarly,
a D0–O4 system realizes the $Sp(0)$ situation. It may be interesting to understand the $Z_k^{Sp(0)}$ from
string theory. Moreover, the AGT correspondence suggests that some symmetries arising from 2d
CFT act on poles of the Nekrasov partition functions. One may construct the AGT proof for $BCD$
cases through understanding their pole distributions.

Appendix A. The Jeffrey–Kirwan residues of the $Sp(0)$ Nekrasov partition function

Here we give a list of all the JK-residues of the $Sp(0)$ Nekrasov partition functions $Z_{k}^{Sp(0)}$ with instanton number $k \leq 8$. We denote the sum of JK-residues over a Weyl orbit $[\phi_{x}]$ by $Z_{k}^{Sp(0)}([\phi_{x}])$.

We denote two boxes by $\square$, and three boxes by $\mathcal{B}$. We omit poles whose residues vanish trivially. From the list, one can get $Z_{k}^{Sp(0)} = \frac{(-1)^k}{24k!e_1^2e_2^2}$ for $k \leq 8$.

A.1. $k = 0, 1, 2, 3$

\begin{align*}
Z_{0}^{Sp(0)}(\square) &= 1 \\
Z_{1}^{Sp(0)}(\square) &= -\frac{1}{2e_1e_2} \\
Z_{2}^{Sp(0)}(\square\square) &= -\frac{1}{8e_{1}^{2}(e_{1} - e_{2})} \\
Z_{2}^{Sp(0)}(\square) &= \frac{1}{8e_{1}^{2}(e_{1} - e_{2})} \\
Z_{3}^{Sp(0)}(\square\square) &= -\frac{1}{24e_{1}^{3}(e_{1} - e_{2})(2e_{1} - e_{2})} \\
Z_{3}^{Sp(0)}(\square) &= \frac{1}{24e_{1}^{3}(e_{1} - e_{2})(e_{1} - 2e_{2})} \\
Z_{3}^{Sp(0)}(\square\square) &= -\frac{3e_{1} + 3e_{2}}{48e_{1}^{2}e_{2}(e_{1} - e_{2})(2e_{1} - e_{2})} \\
Z_{3}^{Sp(0)}(\square) &= \frac{2e_{1} + 3e_{2}}{48e_{1}^{2}e_{2}(e_{1} - e_{2})(2e_{1} - e_{2})}
\end{align*}

A.2. $k = 4$

\begin{align*}
Z_{4}^{Sp(0)}(\square) &= \frac{1}{128e_{1}(e_{1} - 3e_{2})(e_{1} - 2e_{2})(e_{1} - e_{2})e_{2}^{2}} \\
Z_{4}^{Sp(0)}(\square\square) &= \frac{2e_{1} + e_{2}}{64e_{1}^{2}(e_{1} - 2e_{2})^{2}(2e_{1} - e_{2})(3e_{1} - e_{2})e_{2}^{3}} \\
Z_{4}^{Sp(0)}(\square\square\square) &= \frac{3e_{1} + e_{2}}{64e_{1}^{2}(e_{1} - 3e_{2})(e_{1} - 2e_{2})^{2}(3e_{1} - e_{2})e_{2}^{4}} \\
Z_{4}^{Sp(0)}(\square\square) &= \frac{e_{1} - 2e_{2}}{64e_{1}^{2}(e_{1} - 3e_{2})(e_{1} - 2e_{2})(2e_{1} - e_{2})e_{2}^{4}} \\
Z_{4}^{Sp(0)}(\square) &= \frac{1}{32e_{1}(e_{1} - 2e_{2})(e_{1} - e_{2})^{2}(2e_{1} - e_{2})e_{2}^{3}} \\
Z_{4}^{Sp(0)}(\square\square\square) &= \frac{-e_{1} - 2e_{2}}{192e_{1}^{2}(e_{1} - 2e_{2})(e_{1} - e_{2})^{2}e_{2}^{5}} \\
Z_{4}^{Sp(0)}(\square\square\square\square) &= \frac{1}{128e_{1}^{2}(e_{1} - e_{2})(2e_{1} - e_{2})(3e_{1} - e_{2})e_{2}^{2}} \\
Z_{4}^{Sp(0)}(\square\square\square\square) &= \frac{2e_{1} + e_{2}}{192e_{1}^{2}(e_{1} - e_{2})^{2}(2e_{1} - e_{2})(3e_{1} - e_{2})e_{2}^{3}}
\end{align*}

A.3. $k = 5$

\begin{align*}
Z_{5}^{Sp(0)}(\square\square\square\square\square) &= -\frac{1}{640e_{1}(e_{1} - e_{2})(2e_{1} - e_{2})(3e_{1} - e_{2})(4e_{1} - e_{2})e_{2}^{4}} \\
Z_{5}^{Sp(0)}(\square\square\square\square\square\square) &= \frac{3(5e_{1} + 2e_{2})}{1280e_{1}^{2}(3e_{1} - 2e_{2})(e_{1} - e_{2})(2e_{1} - e_{2})(3e_{1} - e_{2})e_{2}^{5}}
\end{align*}
\[ Z_s^{\text{Spin}} \left( \frac{k}{2} \right) = \frac{(3\varepsilon_1 + 2\varepsilon_2)(5\varepsilon_1 + 2\varepsilon_2)}{960r_1^2(\varepsilon_1 - 2\varepsilon_2)(\varepsilon_1 - \varepsilon_2)(\varepsilon_1 - 2\varepsilon_2)^2(2\varepsilon_1 - \varepsilon_2)^2} \]  
(A19)
\[ Z_{6}^{\text{Sp}}(\text{a}) = - \frac{(e_1 + e_2)(5e_1 + e_2)(e_1 + 3e_2)}{512e_1^2(e_1 - 3e_2)(e_1 - 2e_2)(e_1 - e_2)^2(2e_1 - e_2)(3e_1 - e_2)(5e_1 - e_2)e_2^2} \]  
(A42)

\[ Z_{6}^{\text{Sp}}(\text{b}) = - \frac{(3e_1 + e_2)(5e_1 + e_2)}{3072e_1^2(e_1 - 3e_2)(e_1 - 2e_2)(3e_1 - e_2)(5e_1 - e_2)e_2} \]  
(A43)

\[ Z_{6}^{\text{Sp}}(\text{c}) = - \frac{(2e_1 + e_2)(2e_1 + 3e_2)(4e_1 + 3e_2)}{4068e_1^2(e_1 - 3e_2)(e_1 - e_2)^2(2e_1 - e_2)(4e_1 - e_2)e_2^2} \]  
(A44)

\[ Z_{6}^{\text{Sp}}(\text{d}) = - \frac{(e_1 + 2e_2)(e_1 + 3e_2)}{768e_1^2(e_1 - 3e_2)(e_1 - 2e_2)(3e_1 - e_2)(e_1 - e_2)^2(2e_1 - e_2)(5e_1 - e_2)e_2^2} \]  
(A45)

\[ Z_{6}^{\text{Sp}}(\text{e}) = e_1 + 3e_2 \]  
(A46)

\[ Z_{6}^{\text{Sp}}(\text{f}) = - \frac{11}{2304e_1^2(e_1 - 3e_2)(e_1 - 2e_2)(e_1 - e_2)^2(2e_1 - e_2)e_2^2} \]  
(A47)

\[ Z_{6}^{\text{Sp}}(\text{g}) = - \frac{e_1 + 3e_2}{2880e_1^2(e_1 - 4e_2)(e_1 - 3e_2)(e_1 - 2e_2)^2(e_1 - e_2)e_2^2} \]  
(A48)

\[ Z_{6}^{\text{Sp}}(\text{h}) = \frac{1536e_1^2(e_1 - 3e_2)(e_1 - 2e_2)^2(e_1 - e_2)^2(2e_1 - e_2)e_2^2}{(2e_1 + e_2)(e_1 + 2e_2)^2} \]  
(A49)

\[ Z_{6}^{\text{Sp}}(\text{i}) = - \frac{(e_1 + e_2)(e_1 + 2e_2)}{6912e_1^2(3e_1 - e_2)(e_1 - e_2)^2(2e_1 - e_2)^2(3e_1 - e_2)(4e_1 - e_2)e_2} \]  
(A50)

\[ Z_{6}^{\text{Sp}}(\text{j}) = 5(e_1 + 2e_2) \]  
(A51)

\[ Z_{6}^{\text{Sp}}(\text{k}) = 3e_1 + e_2 \]  
(A52)

\[ Z_{6}^{\text{Sp}}(\text{l}) = \frac{(2e_1 + e_2)(2e_1 + 3e_2)(4e_1 + 3e_2)}{708e_1^2(2e_1 - 3e_2)(e_1 - e_2)^2(2e_1 - e_2)(4e_1 - e_2)e_2} \]  
(A53)

\[ Z_{6}^{\text{Sp}}(\text{m}) = \frac{432e_1^2(e_1 - 2e_2)^2(e_1 - e_2)^2(2e_1 - e_2)^2e_2^2}{(e_1 + e_2)^2} \]  
(A54)

\[ Z_{6}^{\text{Sp}}(\text{n}) = \frac{- (2e_1 + e_2)(e_1 + 2e_2)}{96e_1^2(e_1 - 3e_2)(2e_1 - 3e_2)(e_1 - e_2)^2(3e_1 - 2e_2)(e_1 - e_2)^2(2e_1 - e_2)^2e_2^2} \]  
(A55)

\[ Z_{6}^{\text{Sp}}(\text{o}) = \frac{(e_1 + 2e_2)^2(3e_1 + e_2)(3e_1 + 4e_2)}{4608e_1^2(e_1 - 4e_2)(e_1 - 2e_2)^2(3e_1 - 2e_2)(e_1 - e_2)^2e_2^2} \]  
(A56)

\[ Z_{6}^{\text{Sp}}(\text{p}) = \frac{- (2e_1 + e_2)(e_1 + 2e_2)}{96e_1^2(2e_1 - 3e_2)(e_1 - e_2)^2(3e_1 - 2e_2)(e_1 - e_2)^2(2e_1 - e_2)^2(3e_1 - 3e_2)e_2^2} \]  
(A57)

\[ Z_{6}^{\text{Sp}}(\text{q}) = \frac{- 4608e_1^2(e_1 - e_2)(2e_1 - e_2)(3e_1 - e_2)(4e_1 - e_2)(5e_1 - e_2)e_2}{(2e_1 + e_2)(3e_1 + e_2)(3e_1 + 4e_2)} \]  
(A58)

\[ Z_{6}^{\text{Sp}}(\text{r}) = \frac{9216e_1^2(e_1 - e_2)^2(2e_1 - e_2)^2(3e_1 - e_2)e_2^2}{(2e_1 + e_2)(3e_1 + e_2)(3e_1 + 4e_2)} \]  
(A59)

\end{align*}
\]
Note that the numerator in (A129) is not factorized. The degree \(-(4 + 1)\) part appears in its formal series around the pole (A129) and then one should pick up the first degree of the Taylor series of the nonzero factors.

### Appendix B. A comment on the multiplicity factors

To see the relationship between \(A_{\sigma,\eta}\) and the notion of the multiplicity factor in [20], we rephrase the distinction rule as follows.

**Proposition**: Given a graph of the set \(\{Q_1, \ldots, Q_n\} \subset \tilde{Q}^{BCD}\) which is of the form (3.8), the distinction rule for the graph is equivalent to the following condition: for any \(1 \leq i \leq n\), there is a number \(j \geq i\) and at least one of two vectors \(e_i \pm e_j\) (\(e_j\) for \(j = i\)) can be expressed as a non-negative linear combination of \(Q_1, \ldots, Q_n\).

**Proof**: First, we show that the latter condition is satisfied when the graph is \(\eta\)-oriented. We use the notation from Sect. 3.

We first consider a vertex \(v \in V_1 \sqcup V_2\). For the case \((Q_v, e_{m(v)}) = -1\), the sum of the lines in the path between \(v\) and the vertex \(w \neq v\) with \(m(w) = M(v)\) becomes the desired vector for the number \(m(v)\).

For the other case \((Q_v, e_{m(v)}) = +1\), we trace back to the parent vertices of \(v\). Let \(u\) be the parent vertex of \(v\). If \(m(v) < m(u)\), \(Q_v\) is a vector that we want to have. If not, \(u \in V_2 \sqcup V_3 \sqcup V_4 \sqcup V_5\). Here we assume that \(u \in V_2\). Thanks to \(\pm p_u\) in (3.28), there is a line \(Q \neq Q_v\) that satisfies \((Q + Q_v, e_{m(v)}) = 0\). Here we can choose such \(Q\) from \(Q_u\) and the vector \(Q_T\), the line between \(u\) and its descendant tree \(T\) in (3.28). If we can choose \(Q = Q_T\), we see that there exists a vertex \(w\) in \(T\) with \(m(w) = M(u) > m(v)\), and then the sum of all the lines in the unique path between \(v\) and \(w\) becomes a desired vector for the \(m(v)\). If we cannot choose \(Q = Q_T\), we choose \(Q = Q_u\) and repeat the above process.

As a result, we can get a desired vector or a vector \(e_{m(v)} \pm e_{m(u)}\) by a non-negative combination of \(Q_s\), where \(u = u(v)\) is the unique vertex satisfying \(u \in V_3 \sqcup V_4 \sqcup V_5\) and \(v \in D(u)\). We focus on the latter vector. We may assume \(m(u) < m(v)\), or \(e_{m(v)} \pm e_{m(u)}\) is a desired vector.

If \(u \in V_5\), an appropriate path around the loop gives a vector \(e_{m(v)} + e_{m(t)}\) by a non-negative combination of \(Q_s\)’s plus \(e_{m(v)} \pm e_{m(u)}\), where \(t\) is the unique vertex in \(V_3 \sqcup V_4\). Then we go down in the tree of \(t\) to the vertex \(w\) with \(m(w) = n\), and then we get a desired vector \(e_{m(v)} + e_n\). On the other hand, if \(u \in V_3 \sqcup V_4\), the vector \(e_{m(v)} \pm e_{m(u)}\) plus half of the sum of all the lines in the loop becomes a desired vector \(e_{m(v)}\). So we can get a desired vector for each vertex \(v \in V_1 \sqcup V_2\).

Next we consider vertices in the loop. If \(v \in V_3 \sqcup V_5\), repeat the above discussion and get a desired vector for \(m(v)\). If \(v \in V_4\), the sum of all the lines in the path from \(v\) to the vertex \(w\) with \(m(w) = n\) is a desired vector \(e_{m(v)} + e_n\).

As a result, we get a desired vector for each \(1 \leq i \leq n\).

Conversely, we assume the latter condition. Take a vertex \(v\) that is not in the loop of the graph. The rule (3.27) is trivial for the case \(v \in V_1\). For the other case, \(v \in V_2\), an application of the assumption to the vertex \(w \in D(v)\) with \(m(w) = M(v)\) leads to the rule (3.28).

Next, if \(v \in V_3\), we have to make \(e_n\) by a non-negative combination of the \(Q_s\). This leads to rule (3.29). If \(V_3\) is empty, we apply the condition to the vertex \(w\) with \(m(w) = n\), and then
we get the rules (3.30, 3.31) for the case \( v \in V_4 \sqcup V_5 \). As a result, we derive the distinction rule from the latter condition.

Thus, the two conditions are equivalent.

Now we interpret the distinction rule in the box language. We have the following corollaries that judge whether a graph contains an \( \eta \)-oriented subgraph or not.

**COROLLARY** The graph for a pole \( \phi_1 \in \mathbb{C}^n \) contains an \( \eta \)-oriented subgraph if and only if, for each box with number \( 1 \leq i \leq n \) in the box expression of \( \phi_1 \), there is another box with number \( j(>i) \) or character \( j'(j \geq i) \) in its upper-left region in the lattice where the box belongs.

**COROLLARY** The graph for a pole \( \phi_1 \in \mathbb{C}^n \) is \( \eta \)-oriented if and only if, for each box with number \( 1 \leq i \leq n \) in the box expression of \( \phi_1 \), there is a box with number \( j(>i) \) or character \( j'(j \geq i) \) in its upper-left region in the lattice where the box belongs.

The latter corollary provides an algorithm to determine the multiplicity factor that appeared in [20].

**Example** Consider a Weyl orbit whose diagram is of the form \( \[ \square \square \square \] \). The corresponding graph to the diagram is \( \circ \circ \circ \). For the box \( [1] \), at least one of the three boxes \( [1], [2], \text{and } [2'] \) is to the left of \( [1] \). Also, \( [2] \) must lie to the left of \( [2] \). So just the three poles \( [2] [1'] [1], [2'] [1] [1], \text{and } [1] [2] [1] \) give \( \eta \)-oriented graphs.

Similarly, for the diagram \( [\square \square \text{ ] } \), we have just one pole \( [\text{[2] [1]}] \) whose graph is \( \eta \)-oriented. As a result, we have the multiplicity factors \( A_{[\square \square \text{ ] \eta]} = 3 \) and \( A_{[\square \square \text{ ] \eta]} = 1 \).
