Within the framework QCD sum rules, we use the least square fitting method to investigate the first radial excitations of the nucleon and light mesons such as $\rho$, $K^*$, $\pi$, $\varphi$. The extracted masses of these radial excitations are consistent with the experimental data. Especially we find that the decay constant of $\pi(1300)$, which is the first radial excitation of $\pi$, is tiny and strongly suppressed as a consequence of chiral symmetry.

I. INTRODUCTION

The method of QCD sum rules has been widely used to extract the resonance information in hadron physics [1]. This formalism is usually applied to study the ground state in a specific channel due to the limitation of theoretical accuracy and difficulty of numerical analysis. The excitations of mesons have been studied within finite energy sum rules in the literature [2–4]. Recently, there are some attempts to study the excitations of the heavy-light mesons using the method of QCD sum rules [5].

The radial excitations have the same spin-parity as the ground state. Experimentally
many radial excitations of mesons and baryons have been established [6]. Sometimes it is quite difficult to identify the radial excitations of hadrons. For example, the situation of the radial excitations of the vector charmonium above 4 GeV becomes quite unclear after so many charmonium-like XYZ states have been reported experimentally in the past decade. Theoretical investigations of the radial excitations are also very challenging.

In this work, we shall study the first radial excitations of the light mesons and nucleon within the framework of the QCD sum rule formalism. We explicitly keep two poles in the usual spectrum representation. Then we employ the least square method in the numerical analysis to extract the resonance information of the first radial excited state. The extracted masses of the radial excitations of the light mesons and nucleon agree with the experimental data quite well.

The paper is organized as follows. In Section II, we introduce the QCD sum rule formalism and our least-square method. The numerical results are presented in Sections III-VII. The last section is a short summary.

II. FORMALISM

Within the framework of the QCD sum rule approach, we study the correlation function at the quark level

$$\Pi(q) = i \int d^4x e^{iqx} \langle 0 | T \{ j(x) j^\dagger (0) \} | 0 \rangle$$

where $j(x)$ is the interpolating current with the same quantum numbers as the hadrons. The above correlation function satisfies the dispersion relation

$$\Pi(q^2) = \frac{1}{\pi} \int_{s_{\text{min}}} ds \frac{\text{Im} \Pi(s)}{s - q^2 - i\epsilon}$$

At the quark gluon level, the correlation function can be calculated with the operator product expansion. The gluon and quark condensates appear as higher dimensional operators in this expansion. At the hadron level, the spectral density of the correlation function can be expressed in terms of the hadron masses and couplings. Due to the quark hadron duality, we get an equation called the QCD sum rule which relates the correlation function at the quark gluon level to the physical states. After making Borel transformation to the sum rule in the momentum space, one gets

$$\Pi'(M^2) = \frac{1}{\pi} \int e^{-s/M^2} \text{Im} \Pi(s) \, ds$$
where $M$ is the Borel parameter.

The spectral density usually takes the one-pole approximation

$$\rho(s) \equiv \frac{1}{\pi} \text{Im}\Pi(s) = f\delta(s - m^2) + \rho_{\text{continuum}}\theta(s - s_0),$$

where $m$ is the mass of the ground state and $s_0$ is the threshold parameter. Above $s_0$, the spectral density at the hadron level is replaced by the spectral density derived at the quark-gluon level. Now the sum rule reads

$$fe^{-m^2/M^2} = \Pi'(M^2) - \int_{s_0}^{\infty} e^{-s/M^2}\rho_{\text{OPE}}(s)\,ds.$$ 

The usual numerical method in QCD sum rule analysis is to differentiate Eq. (5) with respect to $1/M^2$ and divide the resulting equation by Eq. (5)

$$m^2 = \frac{\int_{s_0}^{\infty} e^{-s/M^2}s\rho_{\text{OPE}}(s)\,ds}{\int_{0}^{\infty} e^{-s/M^2}\rho_{\text{OPE}}(s)\,ds}.$$ 

One usually plots the variation of the mass versus $M^2$ and $s_0$ to find a working window.

However, the method described above can only be applied to the ground states. In order to extract the resonance information of the first radial excitation, we modify the above spectral density and explicitly keep the pole of the first radial excitation in the spectrum. Now the modified spectral density reads

$$\rho(s) \equiv \frac{1}{\pi} \text{Im}\Pi(s) = f_1\delta(s - m^2) + f_2\delta(s - m'^2) + \rho_{\text{continuum}}\theta(s - s'_0).$$

To simplify the numerical analysis, we use the zero width approximation for both the ground state and first radial excitation. The parameters $f_1$ and $f_2$ are related to the coupling parameters while $m$ and $m'$ are the masses of the ground state and the first radial excitation respectively. Now the sum rules read

$$\int e^{-s/M^2}\rho_{\text{ground}}(s)\,ds + \int e^{-s/M^2}\rho_{\text{excitation}}(s)\,ds + \int_{s_0}^{\infty} e^{-s/M^2}\rho_{\text{continuum}}(s)\,ds$$

$$= \Pi'(M^2) = \Pi_{\text{perturbation}}'(M^2) + \Pi_{\text{condensates}}'(M^2).$$

The usual numerical method cannot be applied here because the modified spectrum has two mass parameters. We use the least square method [7] to fit these masses and decay parameters. The detail of the method are described below.

As usual in the sum rule analysis, one has to find an optimal working interval of the Borel parameter $M^2$. The lower boundary of $M^2$ is chosen to ensure the convergence of
the operator product expansion while the upper boundary is chosen to make the continuum contribution remain subleading.

To get an optimal interval of the Borel parameter $M^2$, we set
\[
\left| \int_{s_0}^{\infty} e^{-s/M^2} \rho_{\text{continuum}}(s) \frac{ds}{\Pi'(M^2)} \right| \leq \alpha_1
\]
which ensures that the continuum contribution remains subleading and determines the upper boundary and
\[
\left| \frac{\Pi'_{\text{condensates}}(M^2)}{\Pi'(M^2)} \right| \leq \alpha_2
\]
which ensures that the OPE is reliable and determines the lower boundary. The two boundaries determine the optimal interval of $M^2$ for our numerical analysis.

The number $\alpha_1$ and $\alpha_2$ is chosen to ensure a rational contribution of continuum and higher order OPE terms. For the meson case, we set $\alpha_1 = \alpha_2 = \alpha$ to get a reasonable interval of $M^2$. We use different values for $\alpha_1$ and $\alpha_2$ in the nucleon case. Note that we always try a smaller $\alpha$ in the excitation case since the continuum contribution decreases as the threshold parameter $s_0$ increases. If no reasonable interval of $M^2$ can be got in any way, the sum rule may not be appropriate in our numerical method.

We rewrite the sum rule as
\[
\int e^{-s/M^2} \rho_{\text{ground}}(s) \frac{ds}{\Pi'(M^2)} + \int e^{-s/M^2} \rho_{\text{excitation}}(s) \frac{ds}{\Pi'(M^2)} = g(M^2, s_0) = \Pi'(M^2) - \int_{s_0}^{\infty} e^{-s/M^2} \rho_{\text{continuum}}(s) \frac{ds}{\Pi'(M^2)}
\]
which separates the part of expression with physical parameters from the part with just Borel parameter $M^2$ and threshold $s_0$.

With the above expression of $g(M^2, s_0)$, we can generate a series of points $\{(M^2_i, g(M^2_i, s_0))\}$ by choosing a set $\{M^2_i\}$ within the optimal interval of $M^2$. We uniformly choose $N$ points in the optimal interval of $M^2$. The number $N$ is chosen to be 20 or even larger.

With the sets $\{(M^2_i, g(M^2_i, s_0))\}$, we use the least-square method which minimizes the sum of the squares of the difference between the two sides of the sum rules
\[
\sum_{i=1}^{N} \left| f_1 e^{-\frac{m_i^2}{M^2_i}} + f_2 e^{-\frac{m_i^2}{M^2_i}} - g(M^2_i, s_0) \right|^2 = \text{min}
\]
to get the best fit of the resonance parameters of the ground state and first radial excitation.

The masses of the ground states of the light mesons and nucleon are measured precisely experimentally. The extracted masses from the traditional QCD sum rule formalism with the one-pole approximation agree with the experimental data very well. In our analysis we first use the least square method to reproduce the resonance parameters of the ground states. As expected, the resulting masses are consistent with experimental data and those extracted from the traditional QCD sum rule analysis.

Then we use the extracted masses of the ground states as inputs to extract the resonance parameters of the radial excited states since the less parameters in the fitting will cost less computing resource and lead to relatively more stable results. Moreover, we do not fix the masses of the ground states in Eq. (10) in our numerical analysis. Instead we allow them to vary around the experimental central value within ±5%. In this way, we extract the resonance parameters of the first radial excited states numerically.

We analyze several light mesons and nucleon in the following section. The sum rules of the light mesons can be found in the pioneer paper [1]. The nucleon sum rule with the radiative corrections can be found in Ref. [8]. We collect these sum rules in the appendix.

In our analysis we use the following values for the various condensates and parameters [1, 6, 9]:

\[
\langle \bar{q}q \rangle(2\text{GeV}) = -\left(277^{+12}_{-10}\text{MeV}\right)^3, \quad \langle 0|\mu u + m_d\bar{d}d|0\rangle = -\frac{1}{2}f_\pi^2m_\pi^2 = -1.7 \times 10^{-4}\text{GeV}^4,
\]

\[
m_s(2\text{GeV}) = (95 \pm 5)\text{MeV}, \quad \langle (ss)/\langle \bar{q}q \rangle \rangle = 0.8 \pm 0.3, \quad \langle 0|\alpha_s G_{\mu\nu}G^{\mu\nu}|0\rangle = 0.12^{+0.006}_{-0.012}\text{GeV}^4, \quad \langle 0|\alpha_s (\bar{u}\gamma_\alpha\gamma_5t^au - \bar{d}\gamma_\alpha\gamma_5t^ad)^2|0\rangle = \frac{32}{9}\alpha_s \langle 0|\bar{q}q|0\rangle^2 \simeq 6.5 \times 10^{-4}\text{GeV}^4,
\]

\[
\langle 0|\alpha_s (\bar{u}\gamma_\alpha\gamma_5t^au - \bar{d}\gamma_\alpha\gamma_5t^ad) \sum_{q=u,d,s} q\gamma_\alpha t^aq|0\rangle \simeq -\frac{32}{9}\alpha_s \langle 0|\bar{q}q|0\rangle^2 \simeq -6.5 \times 10^{-4}\text{GeV}^4,
\]

\[
\alpha_s(Q^2) = \frac{4\pi}{(\ln(q^2/\Lambda^2))}, \quad \Lambda = 0.1\text{GeV}, \quad \alpha_s(m_Z) = 0.1184 \pm 0.0007, \quad \alpha_s(1.5\text{GeV}) = 0.353 \pm 0.006.
\]

III. THE \( \rho \) MESON

The interpolating current for the \( \rho \) meson is

\[
j^{(\rho)}_\mu = \frac{1}{2} (\bar{u}\gamma_\mu u - \bar{d}\gamma_\mu d),
\]

and the resulting sum rule can be found in the appendix. The usual single-pole spectral density reads

\[
\rho^{(\rho)}(s) = 6\pi^2 f_\rho^2 \delta (s - m_\rho^2) + \frac{3}{2} \left(1 + \frac{\alpha_s(s)}{\pi}\right) \theta (s - s_0)
\]
Table I: The mass and decay constant of the \( \rho \) ground state with \( \alpha = 0.2 \) and \( N = 40 \).

We also need the double-pole spectral density

\[
\rho^{(\rho)}(s) = 6\pi^2 f_\rho^2 \delta(s - m_\rho^2) + 6\pi^2 f_{\rho'}^2 \delta(s - m_{\rho'}^2) + \frac{3}{2} \left( 1 + \frac{\alpha_s(s)}{\pi} \right) \theta(s - s_0),
\]

where \( f_\rho \) and \( f_{\rho'} \) are defined as

\[
\langle 0 | \bar{q} \gamma_\mu | \rho \rangle = m_\rho f_\rho \epsilon_\mu, \quad \langle 0 | \bar{q} \gamma_\mu | \rho' \rangle = m_{\rho'} f_{\rho'} \epsilon'_\mu
\]

where \( q = u, d \).

We first use the least square method and the traditional one-pole spectrum representation with \( \alpha = 0.2 \) and \( N = 40 \) to extract the mass and decay constant of the \( \rho \) meson. The results are listed in Table I. The parameter \( f_1 \) is related to the decay constant in Eq. (4). The values of "min" are the sum of the squares of the differences in Eq. (10). Only when the value of "min" is much smaller than the parameters \( f_2^2, f_2^2 \) etc, the fit and the extracted decay constants are reliable.

We collect the fitting results with the double-pole spectrum in Table II. Note that the parameter \( m \) in Table II is the input to extract the information of the excited state. We use \( \alpha = 0.1 \) in this case. The threshold \( s_0 \) plays the role of including the first radial excitation in the spectrum while excluding the contribution from the higher excitations. To check the consistency of our fitting and dependence of our results on \( s_0 \), we vary \( s_0 \) in a range. A reliable fitting requires that the mass \( m' \) and decay constant \( f_{\rho'} \) of the first radial excitation should not vary too much with \( s_0 \).

From Table II we have

\[
m = (0.76 \pm 0.01) \text{ GeV}, f_\rho = (194 \pm 6) \text{ MeV}
\]
Table II: Masses and decay constants of the $\rho$ ground state and first radial excitation with $\alpha = 0.1$ and $N = 40$.

which agrees with the $\rho$ meson mass from PDG $m = 0.77$GeV[6] and the experimental measurement of the $\rho$ meson decay constant[10]

$$f_\rho^\text{exp} \simeq 216 (5) \text{MeV}. \quad (16)$$

In order to reduce the dependence on the threshold parameter $s_0$, the extracted values of $m$ and $f_\rho$ are the average values of the numerical values in Table I. From Table II we have

$$m' = (1.33 \pm 0.07) \text{GeV}, f_\rho = (197 \pm 1) \text{MeV}, f_{\rho'} = (151 \pm 16) \text{MeV}. \quad (17)$$

From PDG, the mass of the first radial excitation is $m' = 1.47$ GeV and its width is $\Gamma = 0.40$ GeV. Our extracted $\rho'$ mass is consistent with the experimental data. At present, the decay constant of $\rho'$ has not been measured yet.

IV. THE $\pi$ AND $A_1$ MESONS

We adopt the axial current for the pion and $A_1$ mesons

$$j_{\pi}^{A_1} = \bar{u} \gamma_\mu \gamma_5 d, \quad (18)$$

and the resulting sum rule can be found in the appendix. Besides the $a_1$ pole, the pion also contributes to this sum rule due to the partial conservation of the axial vector current. As
Table III: The mass and decay constant of the $A_1$ meson. We use the least square method and the traditional spectrum representation with $\alpha = 0.3$ and $N = 80$.

A Goldstone boson, the pion mass is tiny. Especially in the sum rule analysis, $m_\pi^2$ is much much less than the Borel parameter $M^2$. We can safely ignore the pion mass and let it be zero in the numerical analysis.

The usual spectrum representation is

$$\rho(s) = \pi f_\pi^2 \delta(s) + \pi f_{A_1}^2 \delta(s - m_{A_1}^2) + \frac{1}{4\pi} \left( 1 + \frac{\alpha_s(s)}{\pi} \right) \theta(s - s_0).$$

(19)

Our modified spectrum representation reads

$$\rho^{(\pi)}(s) = \pi f_\pi^2 \delta(s) + \pi f_{A_1}^2 \delta(s - m_{A_1}^2) + \pi f_{A_1}^2 \delta(s - m_{A_1}^2) + \frac{1}{4\pi} \left( 1 + \frac{\alpha_s(s)}{\pi} \right) \theta(s - s_0),$$

(20)

where $f_\pi, f_{\pi'}, f_{A_1}$ are defined as

$$\langle 0 \mid j_\mu \mid \pi \rangle = if_\pi p_\mu, \langle 0 \mid j_\mu \mid \pi' \rangle = if_{\pi'} p'_\mu, \langle 0 \mid j_\mu \mid A_1 \rangle = m_{A_1} f_{A_1} \epsilon'_\mu.$$  (21)

In the fitting, we use the least square method and the traditional spectrum representation with $\alpha = 0.3$ and $N = 80$ to extract the $A_1$ mass and decay constant. The results are listed in Table III.

In order to extract the resonance parameters of the first excitation of the pion meson, we employ the modified spectrum and allow $f_{A_1}$ and $m_{A_1}$ to vary around the experimental data within $\pm 5\%$. The numerical results are listed in Table IV.
Table IV: Masses and decay constants of the $A_1$ ground state and the first radial excitation of the pion with $\alpha = 0.2$ and $N = 80$.

From Table III we have

$$m_{A_1} = (1.22 \pm 0.06) \text{ GeV}, f_\pi = (135 \pm 1) \text{ MeV}, f_{A_1} = (151 \pm 20) \text{ MeV}. \quad (22)$$

From PDG we have $m_{A_1} = 1.23$ GeV and $\Gamma_{A_1} = 0.40$ GeV. We note that the $A_1$ mass from the fitting is in rough agreement with the experimental data. The extracted pion decay constant agrees with the experimental data \[6\]

$$f_{\pi}^{\text{exp}} = 130\text{MeV}. \quad (23)$$

However, the extracted $A_1$ decay constant is only half of the experimental data \[11\]

$$f_{A_1}^{\text{exp}} = 254 (20) \text{ MeV}. \quad (24)$$

To extract the first radial excitation of the pion meson, we use the experimental data of the $A_1$ decay constant as input in the numerical analysis. The results are collected in Table IV. We have

$$m_{\pi'} = (1.38 \pm 0.06) \text{ GeV}, f_\pi = (123 \pm 1) \text{ MeV}, f_{\pi'} = (0.6 \pm 0.8) \text{ MeV}. \quad (25)$$
The resulting mass of the pion radial excitation agrees with the PDG value very nicely: \( m_{\pi'} = 1.30 \) GeV and \( \Gamma_{\pi'} = 0.40 \) GeV \( [6] \). Note that the extracted numerical value of \( f_{\pi'} \) is not reliable since the parameter \( f_3^2 \) is even smaller than the "min". In this case, we may get a upper bound

\[
|f_3| < \sqrt{\text{min}} \sim 0.0032 \text{GeV}^2
\]  

Accordingly, we get the upper bound for \( f_{\pi'} \)

\[
f_{\pi'} < 0.032 \text{GeV}
\]  

If the value of \( f_{\pi'} \) is larger than 0.032 GeV, we should be able to extract its value through the least square fitting method.

In other words, our numerical analysis demonstrates that the decay constant of the pion radial excitation \( \pi' \) is much smaller than the pion decay constant around 130 MeV. This interesting fact was also noticed by previous theoretical work including lattice simulations \( [3, 4, 12–20] \). In fact, the suppression of the \( \pi' \) decay constant is a consequence of the chiral symmetry breaking. In the chiral limit, the decay constants of the pion and its radial excitations satisfy the following relation \( [21] \)

\[
f_{\pi_n} m_{\pi_n}^2 = 0,
\]  

where \( m_{\pi_n} (n \geq 1) \) is the mass of the pion radial excitation. The pion ground state is massless in the chiral limit as a Goldstone boson, hence its decay constant can be large and nonzero. For the pion radial excitation, its mass is large and nonzero. Therefore its decay constant has to vanish, i.e., \( f_{\pi_1} = 0 \).

V. THE K* MESON

The interpolating current for the \( K^* \) meson is

\[
j_{\mu}^{(K^*)} = \bar{u} \gamma_{\mu} s
\]  

and the resulting sum rule can be found in the appendix. The usual single-pole spectral density reads

\[
\rho(s) = \pi f_{K^*}^2 \delta(s - m_{K^*}^2) + \frac{1}{4\pi} \left( 1 + \frac{a_s(s)}{\pi} \right) \theta(s - s_0).
\]  

(30)
Table V: The mass and decay constant of the $K^*$ ground state. We use the least square method and the traditional spectrum representation with $\alpha = 0.3$ and $N = 20$.

Our modified spectrum representation reads

$$\rho^{(K^*)}(s) = \pi f^2_{K^*}\delta(s - m^2_{K^*}) + \pi f^2_{K^{*'}}\delta(s - m^2_{K^{*'}}) + \frac{1}{4\pi} \left(1 + \frac{\alpha_s(s)}{\pi}\right) \theta(s - s_0), \quad (31)$$

where $f_{K^*}$ and $f_{K^{*'}}$ are defined as

$$\langle 0 \mid j^{(K^*)}_\mu \mid K^* \rangle = m_{K^*} f_{K^*} \epsilon_\mu, \langle 0 \mid j^{(K^{*'})}_\mu \mid K^{*'} \rangle = m_{K^{*'}} f_{K^{*'}} \epsilon'_\mu. \quad (32)$$
The results from the first spectrum representation are listed in Table VI and those from the modified spectrum are listed in Table VII. From Table VI we have

\[ m = (0.89 \pm 0.01) \text{ GeV}, \ f_{K^*} = (210 \pm 7) \text{ MeV}. \]  (33)

From Table VII we have

\[ m' = (1.28 \pm 0.06) \text{ GeV}, \ f_{K^*} = (203 \pm 3) \text{ MeV}, \ f_{K^*'} = (155 \pm 11) \text{ MeV}, \]  (34)

where \( m \) is an input parameter in Table VII. The decay constant of the \( K^* \) was measured to be \[ f_{K^*}^{\text{exp}} \simeq 217 \text{ MeV}. \]  (35)

From PDG, the mass and width of the \( K^* \) are \( m' = 1.41 \text{ GeV}, \Gamma = 0.232 \text{ GeV} \) respectively. Clearly our extracted \( f_{K^*} \) from both fitting agrees with the data. The extracted \( m' \) is also consistent with data.

VI. THE \( \varphi \) MESON

The interpolating current for the \( \varphi \) meson is

\[ j^{(\varphi)}_{\mu} = -\frac{1}{3} \bar{s} \gamma_{\mu} s, \]  (36)

and the resulting sum rule can be found in the appendix. The usual spectrum representation is

\[ \rho(s) = \frac{1}{9} f_{\varphi}^2 \delta(s - m_{\varphi}^2) + \frac{1}{36\pi} \left( 1 + \frac{\alpha_s(s)}{\pi} \right) \theta(s - s_0). \]  (37)

We also use the modified spectrum representation

\[ \rho^{(\varphi)}(s) = \frac{1}{9} f_{\varphi}^2 \delta(s - m_{\varphi}^2) + \frac{1}{9} f_{\varphi'}^2 \delta(s - m_{\varphi'}^2) + \frac{1}{36\pi} \left( 1 + \frac{\alpha_s(s)}{\pi} \right) \theta(s - s_0) \]  (38)

where \( f_{\varphi} \) and \( f_{\varphi'} \) are defined as

\[ \langle 0 | \bar{s} \gamma^\mu s | \varphi \rangle = m_{\varphi} f_{\varphi} \epsilon_\mu, \langle 0 | \bar{s} \gamma^\mu s | \varphi' \rangle = m_{\varphi'} f_{\varphi'} \epsilon'_\mu. \]  (39)

We use the least square method and the traditional spectrum representation with \( N = 20 \). Note that there does not exist a working interval of \( M^2 \) for \( \alpha = 0.2 \). So we use \( \alpha = 0.3 \) here. The results from the first spectrum representation are listed in Table VII and those from the modified spectrum are listed in Table VIII, where \( m \) is the input parameter in Table VIII.
Table VII: The mass and decay constant of the $\varphi$ ground state. We use the least square method and the traditional spectrum representation with $N = 20$ and $\alpha = 0.3$ here.

</tr>
</tbody>
</table>

From PDG, the mass and width of the $\varphi$ ground state are $m = 1.020 \text{ GeV}$ and $\Gamma = 0.004 \text{ GeV}$ while $m' = 1.68 \text{ GeV}$, $\Gamma = 0.20 \text{ GeV}$ for first radial excitation. The decay constant of ground state was measured to be \[ f^{\text{exp}}_\varphi = 233 \text{MeV}. \] (40)

From Table VII we have

$${ m = (1.04 \pm 0.02) \text{ GeV}, f_\varphi = (229 \pm 9) \text{MeV}. }$$ (41)
From Table VIII we have

\[ m' = (1.54 \pm 0.07) \text{GeV}, \quad f_\varphi = (210 \pm 8) \text{MeV}, \quad f_{\varphi'} = (228 \pm 11) \text{MeV}. \]  

(42)

The decay constant of the \( \varphi \) meson from both fittings agrees with the data very well while the extracted mass of the first radial excitation is in rough agreement with the data.

VII. THE NUCLEON

The interpolating current for the nucleon is

\[ \eta = \epsilon^{abc} [u^a T C d^b] \gamma^5 u^c - \epsilon^{abc} [u^a T C \gamma^5 d^b] u^c \]  

(43)

and the resulting sum rule [8] can be found in the appendix. The usual spectrum representation for the nucleon is

\[ \rho^{(N)} (s) = \beta^2 N \delta (s - m^2) + \rho_{\text{continuum}} (s) \theta (s - s_0) \]  

(44)

where

\[ \rho_{\text{continuum}} (s) = \frac{1}{\pi} \text{Im} \Pi (s) \]

\[ = \frac{s^2}{4 (2\pi)^4} \left( 1 + \frac{71 \alpha_s}{12 \pi} - \frac{\alpha_s \ln s}{\pi \mu^2} \right) + \frac{1}{(2\pi)^2} \frac{1}{8} \left( \frac{\alpha_s}{\pi} G^2 \right) - \frac{2}{9} \frac{\langle \bar{q} q \rangle}{\pi^2} \frac{1}{s} \]  

(45)

We also use the modified spectrum representation

\[ \rho (s) = \beta^2 N \delta (s - m^2) + \beta^2 N' \delta (s - m'^2) + \rho_{\text{continuum}} (s) \theta (s - s_0), \]  

(46)

where \( \beta^2_N = 32 \pi^4 \lambda^2_N \), \( \beta^2_{N'} = 32 \pi^4 \lambda^2_{N'} \), and \( \lambda_N \) is the overlapping amplitude of the interpolating current with the nucleon state.

The results from the first spectrum representation are listed in Table IX and those from the modified spectrum are listed in Table X. To get stable results, we have used the nucleon mass and \( \beta^2_N = 2.1 \) from Table IX as input in the numerical analysis of the first radial excitation. From PDG, the nucleon mass is \( m = 0.938 \text{ GeV} \) while the mass and width of its first radial excitation are \( m' = 1.44 \text{ GeV} \) and \( \Gamma' = 0.300 \text{ GeV} \). From Table IX we have

\[ m = (0.93 \pm 0.03) \text{ GeV}. \]  

(47)

From Table X we have

\[ m' = (1.50 \pm 0.04) \text{ GeV} \]  

(48)

which is in rough agreement with the data.
Table IX: The mass of the nucleon ground state with $\alpha_1 = 0.8$, $\alpha_2 = 0.4$ and $N = 20$.

VIII. SUMMARY

In short summary, we have attempted to extract the masses of the first radial excited states of the light mesons and nucleon. In our modified hadronic spectral density, we explicitly keep the pole of the first radial excited states together with the ground state. Requiring that the operator product expansion converge and the continuum contribution be subleading leads to the optimal working interval of the Borel parameter $M^2$. Then a series of "data" points (or pseudo-data points) were produced within this working interval of $M^2$. Using the usual one-pole spectral density, we can extract the mass of the ground state with the least square fitting method, which agrees with the experimental data. Then we use these "data" points and the mass of the ground state as input parameters to extract the mass and the decay constant of the first radial excited state by the least square method, which are in good
agreement with the available data.

The QCD sum rule method has its inherent accuracy limit due to the various approximations adopted within this framework, such as the truncation of the the OPE series of the correlation function, the assumption of the quark-hadron duality, the omission of the decay width in the spectral density, the factorization of the four quark condensates and the uncertainties of the values of the various condensates etc. In our analysis we only include the uncertainty from the fitting using the least square method itself. The least square method with the modified spectrum representation allows us to extract useful information of the first radial excitations, which depends on the accuracy of the sum rules. It will be very interesting to explore whether such a formalism can be applied to the other hadrons.

QCD sum rules of the light mesons and nucleon

For the $\rho$ meson

$$\int ds \ e^{-s/M^2} \rho(s) = \frac{M^2}{2} \left[ 1 + \frac{\alpha_s(M)}{\pi} + \frac{4\pi^2 \langle 0 | m_u \bar{u} u + m_d \bar{d} d | 0 \rangle}{M^4} \right]$$

$$+ \frac{1}{3} \pi^2 \left[ \alpha_s \langle 0 | C_{\mu\nu} G^a_{\mu\nu} | 0 \rangle \right] - \frac{2}{3} \pi^3 \left\langle 0 | \alpha_s \left( \bar{u} \gamma_\mu t^a u - \bar{d} \gamma_\mu t^a d \right)^2 | 0 \rangle \right\rangle$$

$$- \frac{4}{9} \pi^3 \left\langle 0 | \alpha_s \left( \bar{u} \gamma_\mu t^a u - \bar{d} \gamma_\mu t^a d \sum_{q=u,d,s} \bar{q} \gamma_\mu t^a q \right) | 0 \rangle \right\rangle$$

(49)

For the $\pi$ meson

$$\int \ e^{-s/M^2} \rho(s) \ ds = \frac{M^2}{4\pi} \left[ 1 + \frac{\alpha_s(M)}{\pi} + \frac{\pi^2 \langle 0 | m_u \bar{u} u + m_d \bar{d} d | 0 \rangle}{M^4} \right]$$

$$+ \frac{1}{3} \pi^2 \left[ \alpha_s \langle 0 | \not{C}_{\mu\nu} G^a_{\mu\nu} | 0 \rangle \right] - \frac{2}{3} \pi^3 \left\langle 0 | \alpha_s \left( \bar{u} \gamma_\mu t^a u - \bar{d} \gamma_\mu t^a d \right)^2 | 0 \rangle \right\rangle$$

(50)

For the $K^*$ meson

$$\int \ e^{-s/M^2} \rho(K^*) \ ds = \frac{M^2}{4\pi} \left[ 1 + \frac{\alpha_s(M)}{\pi} + \frac{6\pi^2 \langle 0 | m_u \bar{u} u + m_s \bar{s} s | 0 \rangle}{M^4} \right]$$

$$+ \frac{1}{3} \pi^2 \left[ \alpha_s \langle 0 | \not{C}_{\mu\nu} G^a_{\mu\nu} | 0 \rangle \right] - \frac{2}{3} \pi^3 \left\langle 0 | \alpha_s \left( \bar{u} \gamma_\mu t^a u - \bar{s} \gamma_\mu t^a s \right)^2 | 0 \rangle \right\rangle$$

(51)

For the $\varphi$ meson

$$\int \ e^{-s/M^2} \rho(\varphi) \ ds = \frac{M^2}{36\pi} \left[ 1 + \frac{\alpha_s(M)}{\pi} - \frac{6m_u^2 \langle 0 | m_u \bar{u} u + m_s \bar{s} s | 0 \rangle}{M^4} \right]$$

$$+ \frac{1}{3} \pi^2 \left[ \alpha_s \langle 0 | \not{C}_{\mu\nu} G^a_{\mu\nu} | 0 \rangle \right] - \frac{448}{81 \pi^3 \alpha_s} \left\langle 0 | \langle 0 | \bar{q} q | 0 \rangle \right\rangle \right\rangle$$

(52)

For the nucleon

$$\hat{A}_0 + \hat{A}_4 + \hat{A}_6 + \hat{A}_8 = \beta^2 \rho N e^{-m^2/M^2} + \beta^2 N e^{-m^2/M^2}$$

(53)
where
\[ \tilde{A}_0(M^2, W^2) = M^6 E_2 \left[ 1 + \frac{\alpha_s}{\pi} \left( \frac{53}{13} - \ln \frac{W^2}{\mu^2} \right) \right] \]
\[ -\frac{\alpha_s}{\pi} \left( M^4 W^2 \left( 1 + \frac{3W^2}{4M^2} \right) e^{W^2/M^2} + M^6 \varepsilon \left( -\frac{W^2}{M^2} \right) \right) \]
\[ \tilde{A}_4(M^2, W^2) = \frac{b M^2 E_0}{4L} \]
\[ \tilde{A}_6(M^2, W^2) = \frac{4}{3} a^2 \left[ 1 - \frac{\alpha_s}{\pi} \left( \frac{5}{6} + \frac{1}{3} \left( \ln \frac{W^2}{\mu^2} + \varepsilon \left( -\frac{W^2}{M^2} \right) \right) \right) \right] \]

\[ a = - (2\pi)^2 \langle \bar{q}q \rangle, b = (2\pi)^2 \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle, \beta_N = (2\pi)^4 \lambda^2_N, \alpha_s (1\text{GeV}) \approx 0.37 \]

\[ E_0 = 1 - e^{-x}, E_2 = 1 - \left( 1 + x + \frac{1}{2} x^2 \right) e^{-x} \]

with \( x = W^2/M^2, \varepsilon(x) = \sum_n \frac{x^n}{n!.n!} \),

\[ L = \frac{\ln (M^2/\Lambda^2)}{\ln (\mu^2/\Lambda^2)} \]
