Abstract

In a slight different way from the previous one, we propose a modified non-Euclidian transformation on the $\frac{SO(2N+2)}{U(N+1)}$ Grassmannian which give the projected $SO(2N+1)$ Tamm-Dancoff equation. We derive a classical time dependent (TD) $SO(2N+1)$ Lagrangian which, through the Euler-Lagrange equation of motion for $\frac{SO(2N+2)}{U(N+1)}$ coset variables, brings another form of the previous extended-TDHartree-Bogoliubov (HB) equation. The $SO(2N+1)$ random phase approximation (RPA) is derived using Dyson representation for paired and unpaired operators. In the $SO(2N)$ HB case, one boson and two boson excited states are realized. We, however, stress non existence of a higher RPA vacuum. An integrable system is given by a geometrical concept of zero-curvature, i.e., integrability condition of connection on the corresponding Lie group. From the group theoretical viewpoint, we show the existence of a symplectic two-form $\omega$.

1 Introduction

The time dependent Hartree-Bogoliubov (TDHB) theory is the first standard approximation in the many-body theoretical description of a superconducting fermion system [1][2]. It is a good approximation for the ground state of a fermion system with a pairing interaction. The $SO(2N)$ Lie algebra of the fermion pair operators contains the $U(N)$ Lie algebra as a subalgebra. $SO(2N)$ and $U(N)$ denote the special orthogonal group of $2N$ dimensions and the unitary group of $N$ dimensions ($N$: Number of single-particle states of the fermions). The canonical transformation of the fermion operators generated by the Lie operators in the $SO(2N)$ Lie algebra induces the generalized Bogoliubov transformation for the fermions. The Euler-Lagrange equation of motion for $SO(2N)$ $U(N)$ coset variables makes a TDHB equation[3].

For providing a general microscopic means for a unified self-consistent (SC) description for Bose and Fermi type collective excitations in such fermion systems, a new many-body theory has been proposed by Fukutome, Yamamura and one of the present authors (S.N.) standing on the $SO(2N+1)$ Lie algebra of the fermion operators [4]. An induced representation of an $SO(2N+1)$ group has been obtained from a group extension of the $SO(2N)$ Bogoliubov transformation for fermions to a new canonical transformation group. We start with the fact that the set of the fermion operators consisting of creation-annihilation and pair operators forms a larger Lie algebra, the Lie algebra of the $SO(2N+1)$ group. The fermion Lie operators, when operated onto the integral representation of the $SO(2N+1)$ wave function (HW), are mapped into the regular representation of the $SO(2N+1)$ group and are represented by Bose operators. The creation-annihilation operators themselves as well as the pair operators are given by the Schwinger type boson representation [5, 6]. Embedding an $SO(2N+1)$ group into an $SO(2N+2)$ group and using $SO(2N+2)$ $U(N+1)$ coset variables [7][8][9][10], we have developed an extended TDHB theory. This extended TDHB theory applicable to both even and odd fermion-number systems is a SC field (SCF) theory with the same level of the mean field approximation as the usual TDHB theory for even fermion-number systems.

With a slight different way from the Fukutome’s [11], we propose a modified non-Euclidian transformation on the $SO(2N+2)$ $U(N+1)$ Grassmannian which give the projected $SO(2N+1)$ Tamm-Dancoff equation [11]. We derive a classical TD $SO(2N+1)$ Lagrangian which, by through the Euler-Lagrange equation of motion for $SO(2N+2)$ $U(N+1)$ coset variables, brings another form of the previous extended-TDHB equation. The $SO(2N+1)$ random phase approximation (RPA) is derived using Dyson representation (rep) [7] for paired and unpaired operators. In the $SO(2N)$ HB case, a RPA vacuum is obtained and one boson and two boson excited states are realized. We, however, stress non existence of a higher RPA vacuum because an $SO(2N+1)$ spinor function is not integrable. An integrable system is given by a geometrical concept of zero-curvature, i.e., integrability condition of connection on the corresponding Lie group. From the group theoretical viewpoint, we show the existence of a symplectic two-form $\omega$.

This paper is organized as follows: First we give a summary of embedding of $SO(2N+1)$ Bogoliubov transformation into $SO(2N+2)$ group. In section 3 we provide a differential form for boson over $SO(2N+2)$ $U(N+1)$ coset space which brings Dyson rep for paired and unpaired operators. In section 4 we give a matrix-valued generator coordinate and non-Euclidian transformation. In section 5 we derive the classical TD $SO(2N+1)$ Lagrangian. In section 6 the RPA vacuum is obtained using the Dyson rep and the existence of the symplectc two-form $\omega$ is shown. Finally, in the last section, we give some discussions and further perspective.

2
2 Summary of embedding of SO(2N+1) Bogoliubov transformation into SO(2N+2) group

Let $c_{\alpha}$ and $c_{\alpha}^\dagger$, $\alpha = 1, \cdots, N$, be annihilation and creation operators of the fermion satisfying the canonical anti-commutation relations

$$\{c_{\alpha}, c_{\beta}^\dagger\} = \delta_{\alpha\beta}, \quad \{c_{\alpha}, c_{\beta}\} = \{c_{\alpha}^\dagger, c_{\beta}^\dagger\} = 0. \quad (2.1)$$

We introduce the following annihilation and creation operators and pair operators:

$$c_{\alpha}, \quad c_{\alpha}^\dagger, \quad E_{\beta}^\alpha = c_{\alpha}^\dagger c_{\beta}, \quad E_{\alpha\beta} = c_{\alpha} c_{\beta}, \quad E_{\alpha\beta}^\dagger = E_{\beta\alpha}^\dagger = E_{\alpha\beta} = -E_{\beta\alpha}. \quad (\alpha, \beta = 1, \cdots, N) \quad (2.2)$$

The fermion operators (2.2) form an $SO(2N+1)$ Lie algebra. Due to the anti-commutation relation (2.1), the commutation relations for the operators in the $SO(2N+1)$ Lie algebra are

$$[E_{\beta}^\alpha, E_{\gamma}^\delta] = \delta_{\gamma\beta} E_{\delta}^\alpha - \delta_{\alpha\delta} E_{\beta}^\gamma, \quad (U(N) \text{ algebra}) \quad (2.3)$$

$$[E_{\beta}^\alpha, E_{\gamma\delta}] = \delta_{\alpha\delta} E_{\beta\gamma} - \delta_{\alpha\gamma} E_{\beta\delta}, \quad [E_{\alpha\beta}, E_{\gamma\delta}] = 0, \quad (2.4)$$

$$[c_{\alpha}, c_{\beta}] = 2E_{\alpha\beta}, \quad [c_{\alpha}, c_{\beta}] = 2E_{\alpha\beta}, \quad [c_{\alpha}, E_{\beta\gamma}] = \delta_{\alpha\beta} c_{\gamma}, \quad [c_{\alpha}, E_{\beta\gamma}] = 0, \quad (2.5)$$

We omit the commutation relations obtained by hermitian conjugation of (2.4) and (2.5). The $SO(2N+1)$ Lie algebra of the fermion operators contains the $U(N) (= \{E_{\alpha\beta}^\dagger\})$ and the $SO(2N) (= \{E_{\alpha\beta}, E_{\alpha\beta}^\dagger\})$ Lie algebras of the pair operators as sub-algebras.

An $SO(2N)$ canonical transformation $U(g)$ is the generalized Bogoliubov transformation $U$ specified by an $SO(2N)$ matrix $g$

$$U(g)(c, c^\dagger)U^\dagger(g) = (c, c^\dagger)g, \quad g \equiv \begin{bmatrix} a & b \\ \overline{b} & \overline{a} \end{bmatrix}, \quad g^\dagger = gg^\dagger = I_{2N}, \quad \det g = 1, \quad (2.6)$$

$$U(g)U(g') = U(gg'), \quad U(g^{-1}) = U^{-1}(g) = U^\dagger(g), \quad U(I_{2N}) = I_g \text{ (unit operator on } g). \quad (2.7)$$

$(c, c^\dagger)$ is a $2N$-dimensional row vector $((c_{\alpha})_1, (c_{\alpha}^\dagger)_1)$. $a = (a_{\alpha\beta})$ and $b = (b_{\alpha\beta})$ are $N \times N$ matrices. The bar denotes the complex conjugation. The HB ($SO(2N)$) WF $|g> >$ is generated as $|g> = U(g)|0> \quad (|0> : \text{ vacuum satisfying } c_{\alpha}|0> = 0)$. The matrix $g$ is composed of matrices the $a$ and $b$ satisfying the ortho-normalization condition. The $|g>$ is expressed as follows:

$$|g> = <0|U(g)|0> \exp \left(\frac{1}{2}q_{\alpha\beta}c_{\alpha}^\dagger c_{\beta}^\dagger\right)|0>, \quad (2.8)$$

$$<0|U(g)|0> = \overline{\mathbf{F}}_{00}(g) = [\det(a)]^{\frac{1}{2}} = \left[\det(1_N + q\dagger q)\right]^{-\frac{1}{4}} e^{i\tau}, \quad (2.9)$$

$$q = ba^{-1} = -q^T, \quad (\text{variables of the } \frac{SO(2N)}{U(N)} \text{ coset space}), \quad \tau = i\frac{1}{2} \ln \left[\frac{\det(\overline{\mathbf{F}})}{\det(a)}\right], \quad (2.10)$$

where det means determinant and the symbol $\tau$ denotes the transposition.

The canonical anti-commutation relation gives us not only the above Lie algebras but also the other three algebras. Let $n$ be the fermion number operator $n = c_{\alpha}^\dagger c_{\alpha}$. The operator $(-1)^n$ anticommutes with $c_{\alpha}$ and $c_{\alpha}^\dagger$

$$\{c_{\alpha}, (-1)^n\} = \{c_{\alpha}^\dagger, (-1)^n\} = 0. \quad (2.11)$$
Introduce an operator $\Theta$ defined by $\Theta \equiv \theta_a c^\dagger_a - \bar{\theta}_a c_a$. Due to the relation $\Theta^2 = -\bar{\theta}_a \theta_a$, we have

$$e^{\Theta} = Z + X_a c^\dagger_a - \bar{X}_a c_a, \quad \bar{X}_a X_a + Z^2 = 1,$$

$$Z = \cos \theta, \quad X_a = \frac{\theta_a}{\theta} \sin \theta, \quad \theta^2 = \bar{\theta}_a \theta_a. \quad (2.12)$$

From (2.1), (2.11) and (2.13), we obtain

$$e^{\Theta}(c_a, c^\dagger_a, \frac{1}{\sqrt{2}})(-1)^n e^{-\Theta} = (c_\beta, c^\dagger_\beta, \frac{1}{\sqrt{2}})(-1)^n G_X,$$

$$G_X \equiv \left[ \begin{array}{ccc}
\delta_{\beta\alpha} - \bar{X}_\alpha X_\alpha & \bar{X}_\beta X_\alpha & -\sqrt{2Z}X_\beta \\
X_\beta X_\alpha & \delta_{\beta\alpha} - X_\beta \bar{X}_\alpha & \sqrt{2Z}X_\beta \\
\sqrt{2Z}X_\alpha & -\sqrt{2Z}X_\alpha & 2Z^2 - 1
\end{array} \right] \quad (2.14)$$

Let $G$ be the $(2N + 1) \times (2N + 1)$ matrix defined by

$$G \equiv G_X \left[ \begin{array}{ccc}
a & \bar{b} & 0 \\
b & \bar{a} & 0 \\
0 & 0 & 1
\end{array} \right] = \left[ \begin{array}{ccc}
a - \bar{X}Y & \bar{b} + XY & -\sqrt{2Z}X \\
b + XY & \bar{a} - \bar{X}Y & \sqrt{2Z}X \\
\sqrt{2Z}Y & -\sqrt{2Z}Y & 2Z^2 - 1
\end{array} \right], \quad X_\alpha = \bar{a}_\beta Y_\beta - b_\alpha \bar{Y}_\beta, \quad \left( \begin{array}{c}
X_\alpha \\
Y_\alpha \\
\bar{Y}_\alpha
\end{array} \right) = 1,$$

$$\left( \begin{array}{c}
X_\alpha - \sqrt{2} \sqrt{Z} Y_\alpha \\
\bar{Y}_\alpha - \sqrt{2} \sqrt{Z} \bar{Y}_\alpha \\
2Z^2 - 1
\end{array} \right) = 1,$$

$$\text{where } X \text{ and } Y \text{ are the column vector and the row vector, respectively. The } SO(2N+1) \text{ canonical transformation } U(G) \text{ is generated by the fermion } SO(2N+1) \text{ Lie operators. The } U(G) \text{ is an extension of the generalized Bogoliubov transformation } U(g) \text{ to a nonlinear transformation and is specified by the } SO(2N+1) \text{ matrix } G. \text{ We identify this } G \text{ with the } U(G) \text{ of } U(G). \text{ Then } U(G) = U(G_X)U(g) \text{ and } U(G_X) = \exp(\Theta).$$

From (2.6), (2.14) and (2.15) and the commutability of $U(g)$ with $(-1)^n$, we obtain

$$U(G)(c_a, c^\dagger_a, \frac{1}{\sqrt{2}})(-1)^nU^\dagger(G) = (c_\beta, c^\dagger_\beta, \frac{1}{\sqrt{2}})(-1)^n \left[ \begin{array}{ccc}
A_\beta & \bar{B}_\beta & -\frac{\bar{x}_\beta}{\sqrt{2}} \\
B_\beta & \bar{A}_\beta & \frac{x_\beta}{\sqrt{2}} \\
y_\alpha & -\bar{y}_\alpha & z
\end{array} \right], \quad (2.16)$$

$$A_{\alpha\beta} \equiv a_{\alpha\beta} - \bar{X}_\alpha Y_\beta = a_{\alpha\beta} - \frac{\bar{Y}_\alpha y_\beta}{2(1 + z)}, \quad B_{\alpha\beta} \equiv b_{\alpha\beta} + X_\alpha Y_\beta = b_{\alpha\beta} + \frac{x_\alpha y_\beta}{2(1 + z)}. \quad (2.17)$$

By using the relation $U(G)(c, c^\dagger, \frac{1}{\sqrt{2}})U^\dagger(G) = U(G)(c, c^\dagger, \frac{1}{\sqrt{2}})U^\dagger(G)(z + \rho)(-1)^n$ and the third column equation of (2.10), Eq. (2.16) can be written as

$$U(G)(c, c^\dagger, \frac{1}{\sqrt{2}})U^\dagger(G) = (c, c^\dagger, \frac{1}{\sqrt{2}})(z - \rho)G, \quad (2.18)$$

$$G \equiv \left[ \begin{array}{ccc}
A & \bar{B} & -\frac{\bar{x}}{\sqrt{2}} \\
B & \bar{A} & \frac{x}{\sqrt{2}} \\
y & -\bar{y} & z
\end{array} \right], \quad G^\dagger G = G G^\dagger = 1_{2N+1}, \quad \det G = 1, \quad (2.19)$$

$$U(G)U(G') = U(GG'), \quad U(G^{-1}) = U^{-1}(G) = U(G), \quad U(1_{2N+1}) = I_G \text{ (unit operator on } G). \quad (2.20)$$
The Lie algebra \( \tilde{E} \) tors of (2.2) and (2.25) can be denoted in a unified manner as

\[
\text{The above commutation relations in (2.27) are of the same form as (2.3) and (2.4).}
\]

We introduce the indices 
\[
\alpha, \beta, \ldots
\]

Instead of (2.25), it is possible to employ the operators \( \tilde{E}_\beta p \) \( p, q = 0, 1, \ldots, N \) satisfying

\[
\text{The Lie algebra} \tilde{U}(N+1) \text{ is a} U(N+1) \text{ Lie algebra but it is not unitarily equivalent to } U(N+1).
\]
The \(SO(2N+1)\) group is embedded into an \(SO(2N+2)\) group. The embedding leads us to an unified formulation of the \(SO(2N+1)\) regular representation in which paired and unpaired modes are treated in an equal way. Define \((N+1) \times (N+1)\) matrices \(A\) and \(B\) as

\[
A = \begin{bmatrix} A & -\frac{\pi}{2} \\ y & 1 + z \\ 2 & 2 \end{bmatrix}, \quad B = \begin{bmatrix} B & x \\ y & 1 - z \\ -2 & 2 \end{bmatrix}, \quad y = x^T a - x^b. \tag{2.30}
\]

Imposing the ortho-normalization of the \(G\), matrices \(A\) and \(B\) satisfy the ortho-normalization condition and then form an \(SO(2N+2)\) matrix \(G\) [7] represented as

\[
G = \begin{bmatrix} A & B \\ B & A \end{bmatrix}, \quad G^\dagger G = GG^\dagger = 1_{2N+2}, \tag{2.31}
\]

which means the ortho-normalization conditions of the \(N+1\)-dimensional HB amplitudes

\[
A^\dagger A + B^\dagger B = 1_{N+1}, \quad A^T B + B^T A = 0, \quad A A^\dagger + B B^\dagger = 1_{N+1}, \quad A B^\dagger + B A^\dagger = 0. \tag{2.32}
\]

The matrix \(G\) satisfies \(\det G = 1\) as is proved easily below

\[
\det G = \det \left( A - BA^{-1} B \right) \det \overline{A} = \det \left( A A^\dagger - B^\dagger B A \right) = 1. \tag{2.33}
\]

By using (2.17) and (2.15), the matrices \(A\) and \(B\) can be decomposed as

\[
A = \begin{bmatrix} 1_N - \frac{\pi}{2} \\ (1+z) r^T \\ 2 \end{bmatrix}, \quad B = \begin{bmatrix} a & 0 \\ 0 & 1 \end{bmatrix}, \quad B^T \begin{bmatrix} x & 2 \\ -2 & 2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \end{bmatrix}, \tag{2.34}
\]

from which we get the inverse of \(A\), \(A^{-1}\) and a \(SO(2N+2)_{U(N+1)}\) coset variable \(Q\) as

\[
A^{-1} = \begin{bmatrix} a^{-1} & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1_N & \frac{\pi}{2} \\ -r^T & 1 \end{bmatrix}, \quad Q = B A^{-1} = \begin{bmatrix} q & \frac{r}{2} \\ -r^T & 0 \end{bmatrix} = -Q^T. \tag{2.35}
\]

The variables \(q_{\alpha}\) and \(r_{\alpha}\) are independent variables of the \(SO(2N+2)_{U(N+1)}\) coset space. The paired mode \(q_{\alpha}\) and unpaired mode \(r_{\alpha}\) variables in the \(SO(2N+1)\) algebra are unified as the paired variables in the \(SO(2N+2)\) algebra [7]. We denote the \((N+1)\)-dimension of the matrix \(Q\) by the index 0 and use the indices \(p, q, \cdots\) running over 0 and \(\alpha, \beta, \cdots\). Using the \((2N+2) \times (2N+2)\) isometric matrix \(U(U^T = [B^T, A^T], UU^\dagger = 1_{N+1})\), let us introduce the \((2N+2) \times (2N+2)\) matrix \(W\):

\[
W = U U^\dagger = \begin{bmatrix} R & \mathcal{K} \\ -\mathcal{K} & 1_{N+1} - R \end{bmatrix}, \quad R = B B^\dagger, \quad \mathcal{K} = B A^\dagger, \tag{2.36}
\]

which satisfies the idempotency relation \(W^2 = W\) and is hermitian on the \(SO(2N+2)\) group. The \(W\) is a natural extension of the generalized density matrix in the \(SO(2)\) coherent state (CS) rep to that in the \(SO(2N+2)\) CS rep. As was shown also in Ref. [13], both the matrices \(A\) and \(B\) and both the matrices \(R\) and \(\mathcal{K}\) are represented in terms of only \(Q = (Q_{pq})\) as

\[
A = (1_{N+1} + Q^T Q)^{-\frac{1}{2}} \hat{U}, \quad B = Q(1_{N+1} + Q^T Q)^{-\frac{1}{2}} \hat{U}, \quad \hat{U} \in U(N+1), \tag{2.37}
\]

\[
R = \mathcal{Q}(1_{N+1} + Q^T Q)^{-\frac{1}{2}} 1_{N+1} - (1_{N+1} + Q Q^T)^{-1}, \quad \mathcal{K} = \mathcal{Q}(1_{N+1} + Q^T Q)^{-1}. \tag{2.38}
\]

Finally, the Hamiltonian of the fermion system under consideration is given as

\[
H = h_{\alpha \beta} \left( E_\beta^\alpha + \frac{1}{2} \delta_{\alpha \beta} \right) + \frac{1}{4} \left[ \alpha \beta | \gamma \delta \right] E_\alpha^\gamma E_\beta^\delta, \tag{2.39}
\]

in which \(h_{\alpha \beta}\) is a single-particle hamiltonian with a chemical potential and \([\alpha \beta | \gamma \delta] = -[\alpha \delta | \gamma \beta] = [\gamma \delta | \alpha \beta] = -[\beta \alpha | \delta \gamma]\) are anti-symmetrized matrix elements of an interaction potential.
3 Differential form for boson over $\frac{SO(2N+2)}{U(N+1)}$ coset space

The boson images $\mathcal{E}_q^p$ etc. of the operators $E_q^p$ etc. in (2.27) are represented by the closed first order differential forms over the $\frac{SO(2N+2)}{U(N+1)}$ coset space in terms of the $\frac{SO(2N+2)}{U(N+1)}$ coset variables $Q_{pq}$ and the phase variable $\tau \left(= \frac{i}{2} \ln \left[ \frac{\det(A)}{\det(A)} \right] \right)$ of the $U(N+1)$, being identical with that of the $U(N)$, $\tau = \frac{i}{2} \ln \det(A)$, due to the relation $\det A = \frac{1}{2} \det a$, in the following forms:

$$\mathcal{E}_q^p = \overline{Q}_{qr} \frac{\partial}{\partial Q_{rq}} - Q_{qr} \frac{\partial}{\partial Q_{pr}} - i \delta_{pq} \frac{\partial}{\partial \tau}, \quad \mathcal{E}_{pq} = Q_{pr} Q_{qs} \frac{\partial}{\partial Q_{rs}} - i \frac{\partial}{\partial Q_{pq}} - i Q_{pq} \frac{\partial}{\partial \tau}, \quad \mathcal{E}^{pq} = \mathcal{E}_{pq}. \quad (3.1)$$

which are derived in a way quite analogous to the $SO(2N)$ case of the fermion Lie operators. From (3.1), we can get the images of the fermion $SO(2N+1)$ Lie operators, namely, the representations of the $SO(2N+1)$ Lie operators in terms of the variables $q_{\alpha \beta}$ and $r_\alpha$ [14]:

$$E^\alpha_\beta = \mathcal{E}^\alpha_\beta = e^\alpha_\beta + \tau_\alpha \frac{\partial}{\partial \tau_\beta} - r_\beta \frac{\partial}{\partial r_\alpha}, \quad \widetilde{E}_{\alpha \beta} = \mathcal{E}_{\alpha \beta} = e_{\alpha \beta} + (r_\alpha q_{\beta \xi} - r_\beta q_{\alpha \xi}) \frac{\partial}{\partial \tau_\xi}, \quad \epsilon^{\alpha \beta} = \mathcal{E}_{\alpha \beta} = e_{\alpha \beta} = q_{\alpha \gamma} q_{\delta \beta} \frac{\partial}{\partial q_{\gamma \delta}} - \frac{\partial}{\partial q_{\alpha \beta}} + i q_{\alpha \beta} \frac{\partial}{\partial \tau}.$$ \hspace{1cm} (3.2)

$$c_\alpha = \epsilon_{0 \alpha} - \mathcal{E}_{0 \alpha} = \frac{\partial}{\partial r_\alpha} + \overline{r}_\alpha \frac{\partial}{\partial \overline{r}_\alpha} + (r_\alpha \overline{q}_{\xi} - q_{\alpha \xi}) \frac{\partial}{\partial \overline{r}_\xi} - q_{\alpha \xi} \overline{r}_\eta \frac{\partial}{\partial q_{\eta \xi}} + i r_\alpha \frac{\partial}{\partial \tau}, \quad c^\dagger_\alpha = \epsilon_{0 \alpha} - \mathcal{E}_{0 \alpha} = \overline{c}_\alpha = - \overline{c}_\alpha = - \frac{\partial}{\partial \overline{r}_\alpha} + \overline{r}_\alpha \frac{\partial}{\partial r_\alpha} - (\overline{r}_\alpha \overline{q}_{\xi} - \overline{q}_{\alpha \xi}) \frac{\partial}{\partial r_\xi} + \overline{q}_{\alpha \xi} \overline{r}_\eta \frac{\partial}{\partial \overline{q}_{\eta \xi}} - i \overline{r}_\alpha \frac{\partial}{\partial \tau}. \quad (3.3)$$

The vacuum function $\Phi_{00}(G)$ satisfies $c_\alpha \Phi_{00}(G) = 0$ and $c^\dagger_\alpha \Phi_{00}(G) = \overline{c}_\alpha \Phi_{00}(G)$. 

Operating (3.2) and (3.3) on the function $\chi(Q, \tau) \Phi_{00}(G)$, we define the operators $\widetilde{E}_{\alpha \beta}$ etc. as $\widetilde{E}_{\chi(Q, \tau)} \Phi_{00}(G) = \Phi_{00}(G) \widetilde{E}_{\chi(Q, \tau)}$. Then, we get

$$E^\alpha_\beta = \mathcal{E}^\alpha_\beta = e^\alpha_\beta + \tau_\alpha \frac{\partial}{\partial \tau_\beta} - r_\beta \frac{\partial}{\partial r_\alpha}, \quad \widetilde{E}_{\alpha \beta} = \mathcal{E}_{\alpha \beta} = e_{\alpha \beta} + (r_\alpha q_{\beta \xi} - r_\beta q_{\alpha \xi}) \frac{\partial}{\partial \tau_\xi}, \quad \epsilon^{\alpha \beta} = \mathcal{E}_{\alpha \beta} = e_{\alpha \beta} = q_{\alpha \gamma} q_{\delta \beta} \frac{\partial}{\partial q_{\gamma \delta}} - \frac{\partial}{\partial q_{\alpha \beta}} + i q_{\alpha \beta} \frac{\partial}{\partial \tau}.$$ \hspace{1cm} (3.4)

$$\mathcal{E}_{0\alpha} = c_{\alpha} = \frac{\partial}{\partial r_\alpha} + \overline{r}_\alpha \frac{\partial}{\partial \overline{r}_\alpha} + (r_\alpha \overline{q}_{\xi} - q_{\alpha \xi}) \frac{\partial}{\partial \overline{r}_\xi} - q_{\alpha \xi} \overline{r}_\eta \frac{\partial}{\partial q_{\eta \xi}} + i r_\alpha \frac{\partial}{\partial \tau}, \quad \mathcal{E}_{0\alpha} = c^\dagger_{\alpha} = - \overline{c}_\alpha = - \frac{\partial}{\partial \overline{r}_\alpha} + \overline{r}_\alpha \frac{\partial}{\partial r_\alpha} - (\overline{r}_\alpha \overline{q}_{\xi} - \overline{q}_{\alpha \xi}) \frac{\partial}{\partial r_\xi} + \overline{q}_{\alpha \xi} \overline{r}_\eta \frac{\partial}{\partial \overline{q}_{\eta \xi}} - i \overline{r}_\alpha \frac{\partial}{\partial \tau}. \quad (3.5)$$

The $\chi(Q, \tau)$ is not necessarily antisymmetric and valid in a space wider than the $SO(2N+1)$ spinor space. Eq. (3.4) is identical with the Dyson rep $[15, 16, 17]$ for the paired operators if we regard $- \frac{\partial}{\partial q_{\alpha \beta}} - q_{\alpha \beta}$ formally as boson annihilation-creation operators with double indices. Eq. (3.5) is also identical with the Dyson rep for the unpaired operators, regarding $- \frac{\partial}{\partial \overline{r}_\alpha} - \overline{r}_\alpha$ formally as boson annihilation-creation operators with a single index. Equations (3.4) and (3.5) are exact extensions of the Dyson rep to include paired and unpaired modes. They provide a consistent boson formalism covering even and odd fermion-number systems.
4 Matrix-valued generator coordinate and modified non-Euclidian transformation

Consider a fermion state vector $|\Psi\rangle$ corresponding to a function $\Psi(\mathcal{G})$ in $\mathcal{G} \in SO(2N+2)$, 
$$|\Psi\rangle = \int U(\mathcal{G}) | 0 > < 0 | U^\dagger(\mathcal{G}) | \Psi \rangle d\mathcal{G} = \int U(\mathcal{G}) | 0 > \Psi(\mathcal{G}) d\mathcal{G},$$  
(4. 1) and a state $|f\rangle$, an exact representation on the $SO(2N+1)$, 
$$|f\rangle = 2^N \int U(\mathcal{G}) | 0 \rangle \langle 0 | U^\dagger(\mathcal{G}) | f\rangle d\mathcal{G} = 2^N \int |\mathcal{G}\rangle \Phi_0 f(\mathcal{G}) d\mathcal{G},$$  
(4. 2) where $d\mathcal{G}$ and $d\mathcal{G}$ are invariant group integrations over the $SO(2N+2)$ and $SO(2N+1)$ groups. From (4. 1) the invariance of group measure of transformations by any group element leads to 
$$U(\mathcal{G}) |f\rangle = 2^N \int |\mathcal{G}'\rangle \Phi_0 f(\mathcal{G}'\rangle d\mathcal{G},$$  
(4. 3) which shows that the canonical transformation to the $\mathcal{G}$ frame corresponds to a mere left coordinate transformation by $\mathcal{G}'$ of the matrix-valued generator coordinate $\mathcal{G}'$. Let $\mathcal{G}$ and $\mathcal{G}'$ be the $SO(2N+2)$ matrices corresponding to $\mathcal{G}$ and $\mathcal{G}'$, respectively. The $\mathcal{G}$ is given by (2.30) and (2.31). Instead of $\mathcal{G}$, let us introduce the matrix-valued generator coordinate $\mathcal{G}$ in the $\mathcal{G}$ frame by $\mathcal{G} = \mathcal{G}' \mathcal{G}$. Then, conversely, the $\mathcal{G}'$ is represented as 
$$\mathcal{G}' = \left[ \begin{array}{cc} \mathcal{A}' & \mathcal{B}' \\ B' & \mathcal{A} \end{array} \right] = \mathcal{G} \mathcal{G}' = \left[ \begin{array}{cc} \mathcal{A} & \mathcal{B} \\ B & \mathcal{A} \end{array} \right] \left[ \begin{array}{cc} \mathcal{A}' & \mathcal{B}' \\ B' & \mathcal{A}' \end{array} \right] = \left[ \begin{array}{cc} \mathcal{A} \mathcal{A} + \mathcal{B} \mathcal{B} & \mathcal{A} \mathcal{B} + \mathcal{B} \mathcal{A} \\ \mathcal{B} \mathcal{A} + \mathcal{A} \mathcal{B} & \mathcal{B} \mathcal{B} + \mathcal{A} \mathcal{A} \end{array} \right].$$  
(4. 4) From (4. 1) and the definition of $\mathcal{G}$ as $\mathcal{G} = \mathcal{B} \mathcal{A} \mathcal{A}^{-1}$ in the coordinate $\mathcal{G}'$, we obtain the relations 
$$\mathcal{A}' = \mathcal{A} \mathcal{A} + \mathcal{B} \mathcal{B} = \left\{ \mathcal{A} + \mathcal{B} \mathcal{B} \mathcal{B}^{-1} \right\} \mathcal{A} = \left\{ \mathcal{A} + \mathcal{B} \mathcal{Q} \right\} \mathcal{A} = \mathcal{A} \left\{ 1_{N+1} + \mathcal{A}^{-1} \mathcal{B} \mathcal{Q} \right\} \mathcal{A},$$  
(4. 5) 
$$\mathcal{B}' = \mathcal{B} \mathcal{A} + \mathcal{A} \mathcal{B} = \left\{ \mathcal{B} + \mathcal{A} \mathcal{B} \mathcal{B}^{-1} \right\} \mathcal{B} = \left\{ \mathcal{B} + \mathcal{A} \mathcal{Q} \right\} \mathcal{B}.$$  
Similary, from $\mathcal{G}' | \mathcal{G} = 1_{N+1} (\mathcal{A}' | \mathcal{A} + \mathcal{B}' | \mathcal{B} = 1_{N+1})$ and $\mathcal{Q} (\mathcal{Q} = \mathcal{B} \mathcal{A}^{-1})$ in the coordinate $\mathcal{G}$, we have 
$$\mathcal{A} + (\mathcal{B} \mathcal{A}^{-1})^T \mathcal{B} = \mathcal{A} - \mathcal{Q} \mathcal{B} = (\mathcal{A} \mathcal{T})^{-1}.$$  
(4. 6) Define a variable $\mathcal{Q}' = \mathcal{B} \mathcal{A} \mathcal{A}^{-1}$ in the coordinate $\mathcal{G}'$. An $SO(2N+2)$ WF generated by a canonical transformation to $\mathcal{G}'$ frame takes a function of the generator coordinate $\tilde{\mathcal{G}}$: $|\mathcal{G}'\rangle = U(\mathcal{G} \mathcal{G}') | 0 \rangle$ owing to the relation $\mathcal{G}' = \mathcal{G} \tilde{\mathcal{G}}$. Using (4. 1) and (4. 6), the variable $\mathcal{Q}'$ is written as 
$$\mathcal{Q}' = \mathcal{Q} + (\mathcal{A} \mathcal{T})^{-1} \mathcal{Q} \left\{ 1_{N+1} + \mathcal{A}^{-1} \mathcal{B} \mathcal{Q} \right\} \mathcal{A}^{-1} =\mathcal{Q} \left\{ 1_{N+1} + \mathcal{A}^{-1} \mathcal{B} \mathcal{Q} \right\} \mathcal{A}^{-1}.$$  
(4. 7) Let us introduce following matrices $\mathcal{R}$, $\mathcal{P}$ and $\mathcal{E}$: 
$$\mathcal{R} = - (\mathcal{A} \mathcal{T})^{-1} \mathcal{B}, \quad \mathcal{P} = (\mathcal{A} \mathcal{T})^{-1} \mathcal{Q} \mathcal{A}^{-1}, \quad \mathcal{E} = \mathcal{A} \mathcal{B} \mathcal{A}^T = - \mathcal{B} \mathcal{A}^T = - \mathcal{Q} (1_{N+1} - \mathcal{Q} \mathcal{Q}^{-1}.$$  
(4. 8) Then, the $\mathcal{Q}'$ is rewritten as 
$$\mathcal{Q}' = \mathcal{Q} + \mathcal{P} \left\{ (\mathcal{A} - \mathcal{A} \mathcal{R} \mathcal{Q}) \mathcal{A}^{-1} \right\} \mathcal{A}^{-1} = \mathcal{Q} + \mathcal{P} (1_{N+1} \mathcal{A} \mathcal{R} \mathcal{Q}) \mathcal{A}^{-1} = \mathcal{Q} + \mathcal{P} (1_{N+1} - \mathcal{E} \mathcal{P}^{-1},$$  
(4. 9) whose transformation rule causes non-Euclidian properties of the coset variables because the coset variables are quantities defined on the non-commutative $SO(2N+2)$ Grassmann manifold.

Finally, we define the overlap integral of $SO(2N+1)$ WFs 
$$S(\mathcal{G}, \mathcal{G}') = \mathcal{F}_{00} (\mathcal{G} \mathcal{G}) = \langle 0 | U^\dagger (\mathcal{G}) U(\mathcal{G}') | 0 \rangle, \quad S(\mathcal{G}, \mathcal{G}) = 1.$$  
(4. 10) 
Multiplying Eq. (4. 2) by $\langle 0 | U^\dagger (\mathcal{G})$, we have 
$$\Phi_{0f} (\mathcal{G}) = 2^N \int S(\mathcal{G}, \mathcal{G}') \Phi_{0f} (\mathcal{G}') d\mathcal{G}',$$  
(4. 11)
in which it is easily verified that the overlap integral \( S(G, G') \) satisfies
\[
S(G, G') = 2N \int S(G, G'') S(G'', G') dG''.
\] (4.12)

This shows the \( 2^N S(G, G') \) is just the projection operator to the \( SO(2N+1) \) spinor space. Putting \( \tilde{G} = G^t G' \) in (4.10) and using the same representations as those of (4.5), we have
\[
\tilde{T}_{00}(G^t G') = \tilde{T}_{00}(\tilde{G}) = \tilde{T}_{00}(\tilde{G}) = [\det(\tilde{A})]^{\frac{1}{2}},
\] (4.13)
\[
\tilde{G} = \begin{bmatrix} \tilde{A} & \tilde{B} \\ \tilde{B} & \tilde{A} \end{bmatrix} = G^t G', \quad G^t G' = \begin{bmatrix} A^t & B^t \\ B^t & A^t \end{bmatrix}\begin{bmatrix} A' & B' \\ B' & A' \end{bmatrix} = \begin{bmatrix} A^t A' + B^t B' & A^t B' + B^t A' \\ B^t A' + A^t B' & B^t B' + A^t A' \end{bmatrix}.
\] (4.14)

Then, an explicit expression for the overlap integral is obtained as
\[
S(G, G') = \det(\tilde{A})^{\frac{1}{2}} = \det(A^t A + B^t B) = D(Q)\Phi_{00}(G)\tilde{T}_{00}(G'), \quad D(Q) = \det(1 - E P),
\] (4.15)

where
\[
\Phi_{00}(G') = \langle 0 | U^t | G' \rangle = [\det(\tilde{A})]^{\frac{1}{2}}, \quad G' = G\tilde{G}.
\] (4.16)

Through (4.5) and (4.8), computation of a determinant of \( 2 \) spinor space, in which it is easily verified that the overlap integral
\[
S(G, G') = \det(\tilde{A})^{\frac{1}{2}} = \det(A^t A + B^t B) = D(Q)\Phi_{00}(G)\tilde{T}_{00}(G'), \quad D(Q) = \det(1 - E P),
\] (4.17)

By using (4.9), the \( SO(2N+1) \) spinor function \( \Phi_{0f}(G') \) can be written as
\[
\Phi_{0f}(G') = \chi_f(Q) \Phi_{00}(G') = \chi_f(Q + P(1 - E P)^{-1}) D(E P) \Phi_{00}(G) \Phi_{00}(G'), \quad K = P(1 - E P)^{-1}.
\] (4.18)

where \( \chi_f(Q) \) is an anti-symmetric polynomial of \( Q_{pq} \) and \( D(E P) = \det(1 - E P) \frac{1}{2} \). We have used the non-Euclidian transformation (4.9) and (4.16) and (4.17). From (4.18) we have
\[
\Phi_{0f}(G') = \chi_f(Q + K) D(E P) \Phi_{00}(G) \Phi_{00}(G), \quad K = P(1 - E P)^{-1}.
\] (4.19)

A differential formula for \( D(E P) \) with respect to \( \epsilon_{pq} \) is easily given as
\[
\frac{\partial D(E P)}{\partial \epsilon_{pq}} = \frac{\partial \det(1 - E P)}{\partial \epsilon_{pq}} \frac{\partial (1 - E P)_{rs}}{\partial \epsilon_{pq}} = K_{pq} D(E P),
\] (4.20)

where we have used the formula \( \frac{\partial}{\partial \epsilon_{pq}} \det A = (A^{-1})_{pq} \det A \) for a regular matrix \( 1 - E P = ((1 - E P)_{rs}) \). As for the second differential for \( D(E P) \), it is carried out as
\[
\frac{\partial^2 D(E P)}{\partial \epsilon_{rs} \partial \epsilon_{pq}} = \frac{\partial K_{pq}}{\partial \epsilon_{rs}} D(E P) + K_{sr} K_{pq} D(E P) = \begin{bmatrix} P_{qp} - \partial (1 - E P)^{-1} \partial (1 - E P)^{-1} \partial (1 - E P)_{uv} + K_{sr} K_{pq} \end{bmatrix} D(E P),
\] (4.21)

where \( A(K_{qp}, K_{sr}) \) is the anti-symmetrized product of \( K_{qp} K_{sr} \). Then, successive differential calculation to higher orders lead to a general differential formula
\[
\frac{\partial^i D(E P)}{\partial \epsilon_{pq} \cdots \partial \epsilon_{uv}} = A(K_{pq} \cdots K_{uv}) D(E P).
\] (4.22)

Applying the differential formulas of \( D(E P) \) with respect to \( \epsilon_{pq} \cdots \epsilon_{uv} \), the Taylor expansion of \( \chi_f(Q + K) \) in (4.21) with respect to \( K \) is made as follows:
\[
\chi_f(Q + \frac{\partial}{\partial K}) D(E P) = \chi_f(Q) D(E P) + \sum_{p < q} \frac{\partial \chi_f(Q)}{\partial Q_{pq}} \frac{\partial D(E P)}{\partial \epsilon_{pq}} + \cdots
\]
\[
+ \sum_{l = 2, 3,} \sum_{p < q < r} \frac{\partial^l \chi_f(Q)}{\partial Q_{pq} \cdots \partial Q_{uv}} \frac{\partial D(E P)}{\partial \epsilon_{pq} \cdots \partial \epsilon_{uv}} + \cdots .
\] (4.23)
Thus, we obtain an important relation\( \tilde{Q}_0 = -Q_0 \). On the other hand, from (2.37), we have the expressions for \( A_0 \) and \( B_0 \) as
\[
A_0 = (1_{N+1} - \tilde{Q}_0 Q_0)^{-\frac{1}{2}} \tilde{Q}_0, \quad B_0 = Q_0 (1_{N+1} - \tilde{Q}_0 Q_0)^{-\frac{1}{2}} \tilde{Q}_0, \quad \tilde{Q}_0 = 1_{N+1}.
\]

Thus, we obtain an important relation \( \tilde{Q}_0 = -Q_0 \). Let us carry modified quantities \( K \) and \( D \) given by
\[
K = \tilde{Q}_0 (1_{N+1} - \tilde{Q}_0 Q_0)^{-1} \text{ and } \; D(\tilde{Q}_0 Q_0) = [\det(1_{N+1} - \tilde{Q}_0 Q_0)]^\frac{1}{2} D.\]

Then, we have the same types of the differential formulas as (4.20) and (4.22) with respect to \( \tilde{Q}_0 \).

We introduce a new differential operator \( \frac{\partial}{\partial \tilde{Q}_{pq}} = (A_0^{-1})^{pr} (\tilde{A}_0^{-1})_{qs} \frac{\partial}{\partial (\tilde{A}_0^{-1})_{pq}} = \{(A_0^{-1})^{pq} \frac{\partial}{\partial (\tilde{A}_0^{-1})_{pq}}\}_{pq} \).\]

The \( SO(2N+1) \) spinor function \( \chi(\tilde{Q}) \Phi_{00}(G) \) is given in the same way as (4.18) and written as
\[
\chi(\tilde{Q}) \Phi_{00}(G) = \Phi_{00}(\tilde{G}) \Phi_{00}(G) \chi \left\{ \tilde{Q}_0 + (A_0^{-1})^r \frac{\partial}{\partial Q_0} (\tilde{A}_0^{-1}) \right\} D
\]
\[
= \Phi_{00}(\tilde{G}) \Phi_{00}(G) \chi \left\{ \tilde{Q}_0 + (A_0^{-1})^r \frac{\partial}{\partial Q_0} (\tilde{A}_0^{-1}) \right\} \frac{\partial D}{\partial \tilde{Q}_{pq}} \frac{\partial D}{\partial \tilde{Q}_{pq}} + \frac{\partial^2 \chi}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} (\tilde{Q}_0) \frac{\partial D}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} + \cdots
\]
\[
= \Phi_{00}(\tilde{G}) \Phi_{00}(G) \chi \left\{ \tilde{Q}_0 + (A_0^{-1})^r \frac{\partial}{\partial Q_0} (\tilde{A}_0^{-1}) \right\} \frac{\partial D}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} \frac{\partial D}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} + \cdots
\]
\[
= \Phi_{00}(\tilde{G}) \Phi_{00}(G) \chi \left\{ \tilde{Q}_0 + (A_0^{-1})^r \frac{\partial}{\partial Q_0} (\tilde{A}_0^{-1}) \right\} \frac{\partial D}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} \frac{\partial D}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} + \cdots
\]
\[
= \Phi_{00}(\tilde{G}) \Phi_{00}(G) \chi \left\{ \tilde{Q}_0 + (A_0^{-1})^r \frac{\partial}{\partial Q_0} (\tilde{A}_0^{-1}) \right\} \frac{\partial D}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} \frac{\partial D}{\partial \tilde{Q}_{pq} \partial \tilde{Q}_{pq}} + \cdots
\]

where we have used the modified matrix in (4.8) \( \chi(\tilde{Q}) \Phi_{00}(G) = \Phi_{00}(\bar{G}) \Phi_{00}(G) \) \( \chi \left\{ \tilde{Q}_0 + (A_0^{-1})^r \frac{\partial}{\partial Q_0} (\tilde{A}_0^{-1}) \right\} D 
\]

which is called the projected \( SO(2N+1) \) Tamm-Dancoff equation whose original form has already been given in Ref. [11]. The \( E_\lambda \) means an eigenvalue. The \( H(\tilde{Q}, Q) \) and \( S(\tilde{Q}, Q) \) are given soon later. Finally, the eigenvectors \( C_{ab-fg,\lambda}^{nii} \) are Tamm-Dancoff expansion coefficients.
5 Classical TD SO(2N + 1) Lagrangian

In this section we will derive a classical TD SO(2N + 1) Lagrangian describing collective excitations in even and odd Fermion systems, respectively. Following Ref. [11], the Lagrangian of the TD SO(2N+1) equation is given by

\[ \mathcal{L} = -\frac{i}{2} \left( <\Psi | \dot{\Psi} > - <\dot{\Psi} | \Psi > \right) + <\Psi | H | \Psi >, \]  

(5.1)

where the dot denotes time derivative.

Taking a coordinate \( \tilde{G}' \) instead of the generator coordinate \( \tilde{G} \) in (4.13), we use the SO(2N4) WF \( \Phi_{00}(\tilde{G}G^\dagger) = \Phi_{00}(\tilde{G})\Phi_{00}(G)D(Q\overline{Q}) \). As basic preparations, following Fukutome [18], we calculate the double group integration of the overlap integral \( \Phi_{00}(\tilde{G}')S(Q', \overline{Q}')\Phi_{00}(\tilde{G}) \) over the \( \tilde{G} \) and \( \tilde{G}' \). It is made in the following way as

\[ 2^{2N}\int \Phi_{00}(\tilde{G}')D(\tilde{Q}'\overline{Q}')\Phi_{00}(\tilde{G})S(\tilde{Q}', \overline{Q}')\Phi_{00}(\tilde{G})d\tilde{G}d\tilde{G}' \]

\[ = 2^{2N}\int \frac{S(\tilde{Q}', \overline{Q}')\Phi_{00}(\tilde{G}')\Phi_{00}(\tilde{G})}{\Phi_{00}(\tilde{G})}S(\tilde{Q}', \overline{Q}')\Phi_{00}(\tilde{G})d\tilde{G}d\tilde{G}' \]

\[ = \frac{1}{\Phi_{00}(\tilde{G})}2^{2N}\int \left( 2^{N}\int S(G, \tilde{G}')S(\tilde{G}', \tilde{G}G)d\tilde{G}' \right)S(\tilde{G}, \tilde{G})d\tilde{G} \]

\[ = \frac{1}{|\Phi_{00}(\tilde{G})|^2}2^{2N}\int S(G, \tilde{G}')S(\tilde{G}', \tilde{G})d\tilde{G} = \frac{S(\tilde{Q}, \overline{Q})}{|\Phi_{00}(\tilde{G})|^2} = \det \left( 1_{N+1} - Q\overline{Q} \right)^{\frac{1}{2}}, \]

where we have used the property of the projection operator \( 2^{N}S(G, G) \) (4.12). The second equation in (4.10) shows the relation \( S(G, G) = 1 \). Using (5.2), we also have

\[ 2^{2N}\int \Phi_{00}(\tilde{G}'G^\dagger)\Phi_{00}(\tilde{G}')S(\tilde{G}', \tilde{G})\Phi_{00}(\tilde{G})d\tilde{G}d\tilde{G}' = S(G, G) = |\Phi_{00}(\tilde{G})|^2S(\tilde{Q}, \overline{Q}) = 1. \]

(5.3)

Introducing the quantity \( N \) defined as \( N \equiv |\Phi_{00}(G)|[S(\tilde{Q}, \overline{Q})]^{\frac{1}{2}} \), we obtain the relation

\[ \frac{\Phi_{00}(\tilde{G}G^\dagger)}{N} = \Phi_{00}(\tilde{G})D(Q\overline{Q}) \left[ \frac{\Phi_{00}(\tilde{G}G^\dagger)}{|\Phi_{00}(\tilde{G})|} \right] \left[ S(\tilde{Q}, \overline{Q}) \right]^{-\frac{1}{2}} = \Phi_{00}(\tilde{G})D(Q\overline{Q})e^{\frac{i}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}}, \]

(5.4)

owing to the form of expression for \( \Phi_{00}(G) \), (2.23). Then, the first term of (5.1) is computed as

\[ -\frac{i}{2} \left( <\Psi | \dot{\Psi} > - <\dot{\Psi} | \Psi > \right) \]

\[ = -\frac{i}{2}2^{2N}\int S(\tilde{G}', \tilde{G}) \left\{ \frac{\Phi_{00}(\tilde{G}G^\dagger)}{N} \frac{\partial}{\partial t} \left( \frac{\Phi_{00}(\tilde{G}G^\dagger)}{N} \right) \right\} d\tilde{G} \]

\[ = -\frac{i}{2}2^{2N}\int S(\tilde{G}', \tilde{G}) \left\{ \frac{\partial}{\partial t} \left( \frac{\Phi_{00}(\tilde{G}G^\dagger)}{N} \right) \right\} d\tilde{G} \]

\[ + \frac{i}{2} \left( \frac{1}{\Phi_{00}(\tilde{G})} \right) \frac{\partial}{\partial t} \left( \frac{1}{\Phi_{00}(\tilde{G})} \right) S(\tilde{G}', \tilde{G}) \]

\[ e^{-\frac{1}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} \frac{S(\tilde{G}', \tilde{G})S(\tilde{G}', \tilde{G})}{\Phi_{00}(\tilde{G})} e^{\frac{i}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} d\tilde{G}d\tilde{G}' \]

\[ = -\frac{i}{2} \left( \frac{1}{\Phi_{00}(\tilde{G})} \right) e^{-\frac{1}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} \frac{\partial}{\partial t} \left( \frac{S(\tilde{G}', \tilde{G})S(\tilde{G}', \tilde{G})}{\Phi_{00}(\tilde{G})} \right) e^{\frac{i}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} d\tilde{G} \]

\[ + \frac{i}{2} \left( \frac{1}{\Phi_{00}(\tilde{G})} \right) \frac{\partial}{\partial t} \left( \frac{S(\tilde{G}', \tilde{G})S(\tilde{G}', \tilde{G})}{\Phi_{00}(\tilde{G})} \right) e^{-\frac{1}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} d\tilde{G}' \]

\[ = -\frac{i}{2} \left( \frac{1}{\Phi_{00}(\tilde{G})} \right) e^{-\frac{1}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} \frac{\partial}{\partial t} \left( \frac{S(\tilde{G}', \tilde{G})S(\tilde{G}', \tilde{G})}{\Phi_{00}(\tilde{G})} \right) e^{\frac{i}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} d\tilde{G} \]

\[ + \frac{i}{2} \left( \frac{1}{\Phi_{00}(\tilde{G})} \right) \frac{\partial}{\partial t} \left( \frac{S(\tilde{G}', \tilde{G})S(\tilde{G}', \tilde{G})}{\Phi_{00}(\tilde{G})} \right) e^{-\frac{1}{2}[S(\tilde{Q}, \overline{Q})]^{-\frac{1}{2}}} d\tilde{G}'. \]
Using the last relation in (5.2) and \( \frac{\phi_{00}(G)}{\Phi_{00}(G)} = -i \frac{\tau}{2} \), which leads us to the following result:

\[
-\frac{i\hbar}{2} \left( \langle \Psi | \hat{H} | \Psi \rangle - \langle \hat{\Psi} | \hat{H} | \hat{\Psi} \rangle \right) = -\frac{i\hbar}{2} \left( e^{-\frac{i\tau}{2}} \Phi_{00}(G) \left[ S(Q, Q) \right]^{\frac{1}{2}} + \frac{i\hbar}{2} \frac{\partial}{\partial t} \left( e^{-\frac{i\tau}{2}} \frac{S(Q, Q)}{\Phi_{00}(G)} \right) \right) e^{\frac{i\tau}{2}} \Phi_{00}(G) \left[ S(Q, Q) \right]^{\frac{1}{2}}
\]

\[
= \frac{\hbar}{2} \tau - \frac{i\hbar}{4} \left( Q \frac{\partial}{\partial Q} - \tilde{Q} \frac{\partial}{\partial \tilde{Q}} \right) \ln S(Q, Q) - \frac{i\hbar}{2} \frac{\Phi_{00}(G)}{\Phi_{00}(G)} \Phi_{00}(G) S(Q, Q)
\]

Using \( \Phi_{00}(G) \) and the definition \( \langle U(G) | H | U^\dagger(G) \rangle = H(G, G) \), the second term is also calculated as

\[
= 2^{2N} \int \int S(\tilde{G}', \tilde{G}^\dagger) e^{-\frac{i\tau}{2}} \left[ S(Q, Q) \right]^{\frac{1}{2}} \frac{\tilde{G} \tilde{G}^\dagger}{\Phi_{00}(G)} e^{\frac{i\tau}{2}} \left[ S(Q, Q) \right]^{\frac{1}{2}} d\tilde{G} d\tilde{G}'
\]

\[
= 2^{2N} \int \int S(G, \tilde{G}') e^{-\frac{i\tau}{2}} \left[ S(Q, Q) \right]^{\frac{1}{2}} \frac{H(G, G)}{\Phi_{00}(G)} e^{\frac{i\tau}{2}} \left[ S(Q, Q) \right]^{\frac{1}{2}} d\tilde{G} d\tilde{G}'.
\]

Using (5.1) with the aid of (5.6) and (5.7), we finally obtain a classical TD \( SO(2N+1) \)

The Euler-Lagrange equation of motion for the \( \frac{SO(2N+1)}{U(2N+1)} \)-coset variable \( Q_{\alpha \beta} \) is calculated to be

\[
\frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{Q}_{pq}} \right) = -\frac{\partial \mathcal{L}}{\partial Q_{pq}} - \frac{\partial}{\partial Q_{pq}} \ln S(Q, Q) - \frac{\hbar}{4} S(Q, Q) + \frac{\hbar}{4} \dot{Q}_{pq}
\]

(5.9)

and its complex conjugation. Equation (5.9) leads to the different form of the \( SO(2N+1) \)

TDHB equation from the one of the TDHB equation given in Ref. [10]. This form of equation also describes collective excitations in even and odd fermion-number systems, respectively.
6 RPA vacuum and symplectic two-form $\omega$

We are now in a stage to derive an equation for the $SO(2N+1)$ random phase approximation (RPA) which describes collective excitations in even and odd Fermion systems, respectively. Let $G$, $G'$ and $G_0$ be the $SO(2N+2)$ matrices corresponding to $G$, $G'$ and $G_0$, respectively. The $G$ is given by (2.31). Following Fukutome [18], we consider the fluctuation $\tilde{G}$ around the stationary ground state $|G_0\rangle$. It can be regarded as the matrix-valued generator coordinate in the $G$ quasi-particle frame defined by the following relation $\tilde{G} = G_0^\dagger G$:

As shown previously, a state vector in the $SO(2N+1)$ spinor space is in the form of

$$\Phi_{0f}(G_0^f G) = \Phi_{00}(G_0^f G)\chi_f[\overline{Q}(G_0^f G)], \quad \Phi_{00}(\tilde{G}) = \Phi_{00}(G).$$

(6.1)

Using the same representations as those of (4.3) for the relation $\tilde{G} = G_0^\dagger G$, we have

$$\tilde{G} = \begin{bmatrix} \overline{A} & \overline{B} \\ \overline{B} & \overline{A} \end{bmatrix} = G_0^\dagger G = \begin{bmatrix} A_0^\dagger A + B_0^\dagger B & A_0^\dagger \overline{B} + B_0^\dagger \overline{A} \\ B_0^\dagger A + A_0^\dagger B & B_0^\dagger \overline{B} + A_0^\dagger \overline{A} \end{bmatrix}. \quad (6.2)$$

Then, with the aid of the last relation of (4.7), a variable $\overline{Q} = \overline{B}\overline{A}^{-1}$ is written as

$$\overline{Q} = \overline{B} \overline{A}^{-1} = (B_0^\dagger A + A_0^\dagger B)(A_0^\dagger A + B_0^\dagger B)^{-1} = (B_0^\dagger + A_0^\dagger Q)(A_0^\dagger + B_0^\dagger Q)^{-1}$$

$$= (\overline{A}_0)^{-1}[Q + \overline{A}_0 B_0^\dagger (1_{N+1} - \overline{Q}_0) Q]^{-1} (\overline{A}_0)^{-1}$$

$$= (\overline{A}_0)^{-1}[-Q_0 (1_{N+1} - \overline{Q}_0) Q]^{-1} Q (1_{N+1} - \overline{Q}_0)^{-1} (\overline{A}_0)^{-1}, \quad (6.3)$$

where we have used $Q = BA^{-1}$. To reach the last line of (6.3), further we have used the relations $\overline{A}_0 A_0^\dagger + B_0 B_0^\dagger = 1_{N+1}$, $\overline{A}_0 B_0^\dagger = -Q_0 (1_{N+1} - \overline{Q}_0) Q_0$, and $B_0 B_0^\dagger = -Q_0 (1_{N+1} - \overline{Q}_0) Q_0^{-1}$, in which the last two relations can be derived from (4.25). At first glance, the transformation rule (6.3) seems to be very different from the one (4.9) given in the previous section. This is because we here choose the matrix-valued generator coordinate in the $G$ quasi-particle frame defined by the relation $\tilde{G} = G_0^\dagger G$ though before we adopted the matrix-valued generator coordinate in the $G$ quasi-particle frame defined by another relation $\tilde{G} = G_0^\dagger G'$. Hereafter we restrict the $G_0$ to a $g_0$, the $SO(2N)$ HB case. Then, from (4.25), we have

$$\overline{Q}_0 = \overline{q}_0 = a_0^{-1}\left\{[q_0(1 - q_0)q_0]^{-1} - q_0(1 - q_0)q_0^{-1}\right\} a_0^{-1}$$

(6.4)

denoting $\overline{q}$ simply as $q$. In that case, the Dyson rep (3.4) leads to the operators $\overline{e}^i_j$ etc. for even number systems and the commutation relation $[\overline{e}^i_j, \overline{e}^k_l]$ in the following forms:

$$\overline{e}^i_j = \frac{1}{2} \delta_{ij} - \frac{\partial}{\partial q_{ij}}, \quad \overline{e}^i_j = -\frac{\partial}{\partial \omega_A}, \quad \overline{e}^i_j \approx \overline{q}_{ij}$$

(6.5)

Let us introduce new boson annihilation-creation operators $\frac{\partial}{\partial \omega_A}$ and $\omega_A$. Then, the old ones $\frac{\partial}{\partial q_{ij}} \frac{\partial}{\partial q_{ij}}$ and $\overline{q}_{ij}$ are expressed in the linear combination of the new ones as follows:

$$\overline{q}_{ij} = u_{ij,A} \omega_A + v_{ij,A} \frac{\partial}{\partial \omega_A}, \quad (i > j),$$

$$\overline{q}_{ij} = u_{ij,A} \omega_A + v_{ij,A} \frac{\partial}{\partial \omega_A}, \quad (i > j),$$

(6.6)

where the coefficients $u$ and $v$ satisfy the following orthogonal conditions:
\[
\begin{aligned}
\{ u_{ij,A} \bar{u}_{kl,A} - v_{ij,A} \bar{v}_{kl,A} = \delta_{ij,kl}, & \quad (uu^\dagger - vv^\dagger = 1_N), \\
v_{ij,A} u_{kl,A} - v_{kj,A} u_{il,A} = 0, & \quad (vu^T - uu^T = 0).
\end{aligned}
\]  

(6.7)

In (6.6) and (6.7), we have used the summation convention over repeated index \( A \). The inverse transformation to (6.6) is given as follows:

\[
\begin{aligned}
\omega_A &= \sum_{i>j} \left( u_{ij,A} \bar{q}_{ij} + v_{ij,A} \frac{\partial}{\partial q_{ij}} \right), \\
\frac{\partial}{\partial \omega_A} &= \sum_{i>j} \left( v_{ij,A} \frac{\partial}{\partial q_{ij}} + u_{ij,A} \bar{q}_{ij} \right),
\end{aligned}
\]

(6.8)

where the coefficients \( u \) and \( v \) satisfy the other type of the orthogonal conditions:

\[
\begin{aligned}
\sum_{i>j} (u_{ij,A} u_{ij,B} - v_{ij,A} \bar{v}_{ij,B}) = \delta_{AB}, & \quad (u^\dagger u - v^\dagger v = 1_N), \\
\sum_{i>j} (u_{ij,A} \bar{v}_{ij,B} - u_{ij,B} \bar{v}_{ij,A}) = 0, & \quad (v^T \bar{v} - u^T u = 0).
\end{aligned}
\]

(6.9)

We here put \( f = 0 \) in the function \( \chi_f \) given in (6.1). This means that we treat only the ground state with no bosons. Then, the function \( \chi_0 \) should satisfy the following condition:

\[
\frac{\partial \chi_0}{\partial \omega_A} = \sum_{i>j} \left( u_{ij,A} \frac{\partial}{\partial q_{ij}} + v_{ij,A} q_{ij} \right) \chi_0 = 0,
\]

(6.10)

where we have used the second equation of (6.8). From (6.10), we can get the differential equation for \( \chi_0 \) with respect to the variable \( \bar{q}_{ij} \) as

\[
\begin{aligned}
\frac{\partial \chi_0}{\partial \bar{q}_{ij}} &= - \sum_{k>l} R_{ij,kl} \bar{q}_{ij} \chi_0, \\
R_{ij,kl} &= [(u^\dagger)^{-1} v^T]_{ij,kl} = [v(\bar{v})^{-1}]_{ij,kl}, \quad R_{ij,kl} = R_{kl,ij}.
\end{aligned}
\]

(6.11)

the solution for which is easily obtained as

\[
\chi_0 = \exp \left[ - \frac{1}{2} \sum_{i>j, k>l} R_{ij,kl} \bar{q}_{ij} \bar{q}_{kl} \right],
\]

(6.12)

which leads to the RPA vacuum \( \Phi_0 = \Phi_{00} (G^\dagger_0 G) \chi_0 \).

On the other hand, by using the boson creation operator \( \omega_A \) (6.8), the RPA excited states with one boson and two bosons can be realized, respectively, in the following forms:

One boson excited state:

\[
\omega_A \chi_0 = \sum_{i>j} \left( u_{ij,A} \bar{q}_{ij} + v_{ij,A} \frac{\partial}{\partial q_{ij}} \right) \chi_0
= \sum_{i>j} (u_{ij,A} \bar{v}_{ij,A} R_{ij,kl} \bar{q}_{ij} \chi_0 = \sum_{i>j} [u^T - v^\dagger v(\bar{v})^{-1}]_{ij,A} \bar{q}_{ij} \chi_0
\]

(6.13)

where we have used the definition of \( R_{kl,ij} \) given by the second equation of (6.11).

Two bosons excited state:

\[
\omega_A \omega_B \chi_0 = \left\{ [(\bar{v})^{-1} \bar{q}]_A [(\bar{v})^{-1} \bar{q}]_B + [(\bar{v})^{-1} \bar{v}]_{AB} \right\} \chi_0.
\]

(6.14)

Finally, we point out the non existence of the higher RPA vacuum. Suppose the function \( \chi \) corresponds to the higher RPA vacuum. Then, the \( \chi \) contains no excited bosons. This is shown as follows: The function \( \chi \) should satisfy the condition

\[
\sum_{i>j} (\bar{u}_{ij,A} \bar{e}_{ij} - v_{ij,A} \bar{e}^{ij}) \chi = 0 \quad \rightarrow \bar{e}_{ij} \chi = R_{ij,kl} \bar{e}^{kl} \chi.
\]

(6.15)
Using the Dyson rep (3.4), this condition (6.15) is transformed to
\[ \left\{ \frac{\partial}{\partial q_{ij}} + R_{ijkl} \left( \overline{q}_{km} \overline{q}_{nl} \frac{\partial}{\partial q_{mn}} + \overline{q}_{kl} \right) \right\} \chi = 0 \rightarrow (1 - R \overline{q}^2) \frac{\partial}{\partial q_{ij}} \chi = -R \overline{q} \chi, \]
from which we have
\[ \frac{\partial}{\partial q_{ij}} \ln \chi = - \left[ (1 - R \overline{q}^2)^{-1} R \overline{q} \right]_{ij}. \] (6.17)

Further the second differential for \( \ln \chi \) with respect to \( \overline{q} \) is computed as
\[ \frac{\partial^2}{\partial q_{kl} \partial q_{ij}} \ln \chi = \frac{\partial f_{ij}}{\partial q_{kl}} \]
\[ = - \left[ (1 - R \overline{q}^2)^{-1} R \right]_{ij, \ kl} - 2 \left[ (1 - R \overline{q}^2)^{-1} R \right]_{ij, \ lm} \overline{q}_{mn} \overline{q}_{nl} \left[ (1 - R \overline{q}^2)^{-1} R \right]_{ln} \] (6.18)
which shows \( \ln \chi \) not to be integrable. An integrability condition is intimately related to the Pfaff’s problem [19] completely solved by Cartan [20]. Thus the non existence of the higher RPA vacuum is proved. A curvature \( C(= d \Omega - \Omega d \Omega) \) to become zero is nothing but the vanishing of the curvature \( C \) of connection. A one-form \( \Omega \) is linearly composed of some infinitesimal generators [21]. The one boson excited state on the the function \( \chi \) is constructed as
\[ \omega_A \chi_0 = \sum_{i>j} \left( u_{ij,A} \overline{e}^i \overline{e}^j - \overline{v}_{ij,A} \overline{e}^i \overline{e}^j \right) \chi_0 \]
\[ = \sum_{i>j} \left( u_{ij,A} \left( \overline{q}_{ij} + \overline{q}_{ik} \overline{q}_{lj} \frac{\partial}{\partial q_{kl}} \right) + \overline{v}_{ij,A} \frac{\partial}{\partial q_{ij}} \right) \chi \]
\[ = \sum_{i>j} \left( u_{ij,A} \overline{q}_{ij} - \overline{q}_{ik} \overline{q}_{lj} \right) - \overline{v}_{ij,A} f_{ij} \chi. \] (6.19)

From the group theoretical viewpoint [21], we show the existence of homogeneous symplectic two-form \( \omega \). We introduce a hermitian and traceless HB density-matrix \( w \) on the \( \overline{SO(2N+2)}_{U(N+1)} \)
\[ w = \overline{G} \in \mathbb{C}^{(N+1) \times (N+1)} \]
\[ \mathbb{C}[-1_N, 0] \quad \begin{bmatrix} 2BB^t - 1_{N+1} & 2BA^t \\ -2BA^t & -2BB^t + 1_{N+1} \end{bmatrix} \]
\[ = \mathcal{W} - 1_{2N+2}, \quad w^a = 1_{2N+2}, \quad (6.20) \]
with \( w \) and \( dw \) zero. The action of \( SO(2N+2) \) on \( w \) is made as \( w \rightarrow \overline{G} w \overline{G}^T \). Taking a new \( (N+1) \times (2N+2) \) matrix \( h \) as \( h^i = (1_{N+1} + \mathcal{Q} \psi^i) \)^{\frac{1}{2}} [1_{N+1} - \mathcal{Q}] \) with \( h^i h_i = 1_{2N+2} \), we have a very simple expression for \( w \) as
\[ w = 1_{2N+2} - 2 h h^\dagger, \quad \text{Tr} w = 0, \] (6.21)
Following Rajeev, Toprak and Tugurt [22, 23, 24, 25], the invariant \( \omega \) and \( d \omega \) are given as
\[ \omega = \frac{-i}{8} \text{Tr} \{ w (dw)^2 \} \] (invariant under \( w \rightarrow \overline{G} w \overline{G}^T \), \( d \omega = \frac{-i}{8} \text{Tr} \{ (dw)^3 \} = \frac{-i}{8} \text{Tr} \{ (dw)^3 w^2 \} = -d \omega \) (6.22)
and then, \( d \omega = 0 \) (closed form). If we introduce hermitian matrices \( \Psi = \begin{bmatrix} 0 & \psi^\dagger \\ \psi & 0 \end{bmatrix} \) and \( \Phi = \begin{bmatrix} 0 & \phi^\dagger \\ \phi & 0 \end{bmatrix} \),
tangent vectors satisfying \( \{ \epsilon, \Psi \} = \{ \epsilon, \Phi \} = 0 \), thus, we have the Rajeev’s quadratic form:
\[ \omega(\Psi, \Phi) = \frac{-i}{8} \text{Tr} \left\{ \begin{bmatrix} 1_N & 0 \\ 0 & -1_N \end{bmatrix} [\Psi, \Phi] \right\} = \frac{i}{4} \text{Tr} \left\{ \psi^\dagger \phi - \phi^\dagger \psi \right\}, \] (6.23)
which is a symplectic and nondegenerate form. The Grassmannian \( w \) is a symplectic manifold with the two-form \( \omega \). A symplectic vector field \( V_\psi (w) \) satisfying \( w V_\psi (w) + V_\psi w = 0 \) is found to be \( V_\psi (w) = -i [\psi, w] \). This is the action of \( V_\psi (w) \) on the \( w \) for a Lie algebra element \( \psi (w) \). The symplectic structure can be considered in terms of the Poisson algebra of these functional matrices. Standing on the above observation, it makes possible to construct the geometric quantization on a finite-dimensional Grassmannian as has been discussed in Ref. [22].
7 Discussions and further perspective

A different form of the $SO(2N+1)$ TDHB theory from the previous one of Ref. [10] has been made, basing on the fact that the fermion annihilation-creation and pair operators form the Lie algebra of $SO(2N+1)$ group. The $SO(2N+1)$ group was found by a group extension of the $SO(2N)$ Bogoliubov transformation for the fermion to a new canonical transformation group. Embedding the $SO(2N+1)$ group into the $SO(2N+2)$ group and using the $SO(2N+2)$ coset variables, we have developed the extended TDHB theory in which paired and unpaired modes are treated in an equal manner. Such the TDHB theory applicable to both even and odd fermion-number systems is also the TDSCF theory with the same level of the mean field approximation as the usual TDHB theory for even fermion-number systems [26, 27].

Adopting a slight different way from Fukutome’s [11], we here have proposed the non-Euclidian transformation, bringing the projected $SO(2N+1)$ Tamm-Dancoff equation of Ref. [11] and derived the classical TD $SO(2N+1)$ Lagrangian which, through the Euler-Lagrange equation of motion for $SO(2N+2)$ coset variables, leads to a different form of the extended TDHB equation from that of Ref. [10]. The RPA, starting with HB approximation [23, 29] for a ground state, HB RPA, has been applied to superconducting fermion systems. The HB RPA, however, is applicable only to even fermion-number systems because the HB WF contains only components with even fermion numbers and describes only Bose type excitations which are ascribed to creation and annihilation of quasi-particle pairs. The present RPA is derived using the Dyson rep [7] for paired and unpaired operators. In the $SO(2N)$ HB case, the RPA vacuum has been obtained. One boson and two boson excited states have also been realized. We, however, have stressed the non existence of the higher RPA vacuum because the $SO(2N+1)$ spinor function is not integrable and existence of the symplectic two-form $\omega$.

Being described in the previous section, the symplectic structure is considered in terms of the Poisson algebra. Along the same as the Rajeev’s method [22], it is possible to construct the geometric quantization on the finite-dimensional Grassmannian $U(N+1)/SO(2N+2)$. According to Ref. [13], if we take matrix elements of $Q$ and $\overline{Q}$ as coordinates on the coset manifold, the real line element is defined by a hermitian metric tensor on the coset manifold as $ds^2=\omega_{pqrs}dQ^p d\overline{Q}^q=\omega_{rs}^{\overline{Q}}=\omega_{rs}^{Q}$. We also use the indices $r_0$, $s_0$, $\cdots$ running over $0$ and $\alpha$, $\beta$, $\cdots$. The hermitian metric tensor $\omega_{pqrs}$ is given through a Kähler potential, $K$ is defined by $\ln\det(1_{N+1}+Q^\dagger Q)$ and its expression is given as $\omega_{pqrs}=\frac{\partial^2 K(Q, Q^\dagger)}{\partial Q^p \partial Q^q}$. Concerning the Poisson bracket, see textbook, e.g., [30]. The Poisson bracket on the complex manifold for a pair of functions $f$ and $g$ is defined by $\{f, g\}=-\omega_{pqrs} \partial f \partial Q^r \partial g \partial Q^s \partial Q^p \partial Q^q$ which is antisymmetric and satisfies the Jacobi identity. The Hamiltonian operated on the function $\chi$, the part of the $SO(2N+1)$ spinor function, is the operator $\overline{H}(\chi)$ coinciding with $H(\overline{Q}, Q)$. While we have the relation $H(\overline{Q}, Q)=\frac{H(G,G)}{\Phi_0(G)} \equiv \langle H \rangle_{G,G}$, whose explicit expression, using (2.39), is obtained as $\langle H \rangle_{G,G}=h_\alpha R_\alpha \frac{1}{2} \frac{1}{\alpha \beta} [\gamma \delta] R_\beta R_\gamma - K_{\alpha \gamma} K_{\delta \beta}$ and the SCF HB hamiltonian $\langle H \rangle_{G,G}$ as $\langle H \rangle_{G,G}=\mathcal{F}_{\alpha \beta} R_\alpha R_\beta + \frac{1}{2} D_{\alpha \beta} K_{\alpha \beta} - \frac{1}{2} \mathcal{D}_{\alpha \beta} K_{\alpha \beta}$ where the SCF parameters $\mathcal{F}_{\alpha \beta}$ and $D_{\alpha \beta}$ are defined as $\mathcal{F}_{\alpha \beta} \equiv \frac{1}{2} \alpha \beta + \frac{1}{2} \gamma \delta$, $D_{\alpha \beta} \equiv \frac{1}{2} [\alpha \beta] [\gamma \delta] K_{\delta \beta}$, respectively. Both the $\langle H \rangle_{G,G}$ and $\langle H \rangle_{G,G}$ become the quadratic functions of the $w$ through $W=\frac{1}{2} (w^2 + l_{2N+2})$. These are the classical systems having the two-form $\omega$ under the constraint $w^2 = l_{2N+2}$ In a near future, we will give a geometric quantization of the above classical systems, following the ways, e.g., Hurt’s [31] or Kirillov’s [32].
