\textit{E-mail: costas.papadopoulos@cern.ch}

In this talk we present the Simplified Differential Equations (SDE) Approach for Master Integrals (MI). Combined with the integrand reduction method for two-loop amplitudes it can pave the road for a fully automated NNLO calculation framework. Most recent achievements of the method, including double-box and pentabox MI calculations, are highlighted.

1. Introduction

With LHC delivering collisions at the highest energy achieved so far, 13 TeV, experiments are providing measurements of physical observables with an unprecedented precision. In order to keep up with the increasing experimental accuracy as more data is collected, more precise theoretical predictions and higher loop calculations are required [1].

With the better understanding of the reduction of one-loop amplitudes to a set of Master Integrals (MI) based on unitarity methods [2, 3] and at the integrand level via the OPP method [4, 5], one-loop calculations have been fully automated in many numerical tools [6, 7]. In the recent years, a lot of progress has been made towards the extension of these reduction methods to the two-loop order at the integral [8, 9] as well as at the integrand [10, 11, 12, 13] level. The master equation at the integrand level can be given schematically as follows [13]

\[
\frac{N(l_1, l_2; \{p_i\})}{D_1D_2 \ldots D_n} = \sum_{m=1}^{\min(n, 8)} \sum_{S_{m,n}} \frac{\Delta_{i_1i_2 \ldots i_m}(l_1, l_2; \{p_i\})}{D_{i_1}D_{i_2} \ldots D_{i_m}}.
\] (1.1)

where an arbitrary contribution to the two-loop amplitude (left), can be reduced to a sum of terms (right) of all partitions \(S_{m,n}\), with up to eight denominators; \(l_1, l_2\) are the loop momenta, \(D_i\) are the inverse scalar Feynman propagators, \(N(l_1, l_2; \{p_i\})\) is a general numerator polynomial and \(\Delta_{i_1i_2 \ldots i_m}(l_1, l_2; \{p_i\})\) are the residues of multivariate polynomial division. In addition \(R_2\) terms [5] have to be studied at two loops in order to achieve a complete framework. Moreover, two remarks are in order here. The first is that the basis of two-loop integrals does not include only scalar integrals. It includes integrals that also have irreducible scalar products (ISP) as numerators (to some power) that cannot be rewritten as existing denominators of the integral. In the one-loop case these ISP are always spurious and integrate to zero, but for higher loops this does no longer hold. The second remark is that if one is interested in constructing an integral basis, the set of integrals that ends up with is not necessarily a minimal one: the integrals are not by default Master Integrals. At two or more loops one can find them by using integration-by-parts (IBP) identities [14, 15, 16, 17, 18].

Contrary to the MI at one-loop, which have been known for a long time already [19], a complete library of MI at two-loops is still missing. At the moment this seems to be the main obstacle to obtain a fully automated NNLO calculation framework similar to the one-loop case, that will satisfy the anticipated precision requirements at the LHC [20].

2. The Simplified Differential Equations Approach

In the last fifteen years, the calculation of virtual corrections has been revolutionized with the advent of automated reduction techniques to MI [15, 14, 16, 21] and the development of systematic solutions of differential equations [22, 23, 24, 25] satisfied by MI or the evaluation of their Mellin-Barnes representations [26, 27]. The differential equations approach (DE) has proven to be very powerful in a large number of computations, including two-loop four-point functions with massless and massive internal propagators. Within this framework, DE for the MI are derived, in terms of kinematical invariants. Assume that one is interested in calculating an \(l\)-loop Feynman integral
with external momenta \( \{p_j\} \) and internal propagators that are massless. Any \( l \)-loop Feynman integral can be then written as

\[
G_{a_1 \cdots a_n}(\{p_j\}, x) = \frac{1}{D_1 \cdots D_n^{\varepsilon}}, \quad D_i = (c_{ij}k_j + d_{ij}p_j)^2, \quad d = 4 - 2\varepsilon \tag{2.1}
\]

with matrices \( \{c_{ij}\} \) and \( \{d_{ij}\} \) determined by the topology and the momentum flow of the graph, and the denominators are defined in such a way that all scalar product invariants can be written as a linear combination of them. The exponents \( a_i \) are integers and may be negative in order to accommodate irreducible numerators. Any integral \( G_{a_1 \cdots a_n} \) can be written as a linear combination of a finite subset of such integrals, called Master Integrals, with coefficients depending on the independent scalar products, \( s_{ij} = p_i \cdot p_j \), and space-time dimension \( d \), by the use of integration by parts identities \([15, 14]\). In the traditional DE method, the MI \( \tilde{G}^{MI}(\{s_{ij}\}, x) \), are differentiated with respect to \( p_i \frac{\partial}{\partial p_i} \), and the resulting integrals are reduced by IBP to give a linear system of DE for \( \tilde{G}^{MI}(\{s_{ij}\}, x) \) \([22, 28]\). The invariants, \( s_{ij} \), are then parametrised in terms of dimensionless variables, defined on a case by case basis, so that the resulting DE can be solved in terms of Goncharov Polylogarithms (GPs) \([29, 30]\). The GPs are defined recursively as follows

\[
\mathcal{G}(a_1, \ldots, a_n, x) = \int_0^x dt \frac{1}{t-a_n} \mathcal{G}(a_{n-1}, \ldots, a_1, t) \tag{2.2}
\]

with the special cases, \( \mathcal{G}(x) = 1 \) and \( \mathcal{G}(0, \ldots, 0, x) = \frac{1}{n!} \log^n(x) \). Usually boundary terms corresponding to the appropriate limits of the chosen parameters have to be calculated using for instance expansion by regions techniques \([31, 32]\).

SDE approach \([33]\) is an attempt not only to simplify, but also to systematize, as much as possible, the derivation of the appropriate system of DE satisfied by the MI. To this end the external incoming momenta are parametrized linearly in terms of \( x \) as \( p_i(x) = p_i + (1 - x)q_i \), where the \( q_i \)’s are a linear combination of the momenta \( \{p_i\} \) such that \( \sum q_i = 0 \). If \( p_i^2 = 0 \), the parameter \( x \) captures the off-shell-ness of the external legs. The class of Feynman integrals in (2.1) are now dependent on \( x \) through the external momenta:

\[
G_{a_1 \cdots a_n}(\{s_{ij}\}, x) = \frac{1}{D_1 \cdots D_n^{\varepsilon}}, \quad D_i = (c_{ij}k_j + d_{ij}p_j(x))^2 \tag{2.3}
\]

By introducing the dimensionless parameter \( x \), the vector of MI \( \tilde{G}^{MI}(\{s_{ij}\}, x) \), which now depends on \( x \), satisfies

\[
\frac{\partial}{\partial x} \tilde{G}^{MI}(\{s_{ij}\}, x) = H(\{s_{ij}\}, x) \tilde{G}^{MI}(\{s_{ij}\}, x) \tag{2.4}
\]

a system of differential equations in one independent variable. Experience up to now shows that this simple parametrization can be used universally to deal with up to six kinematical scales involved \([33, 34, 35]\). The expected benefit is that the integration of the DE naturally captures the expressibility of MI in terms of GPs and more importantly makes the problem independent on the number of kinematical scales (independent invariants) involved. Note that as \( x \rightarrow 1 \), the original configuration of the loop integrals (2.1) is reproduced, which eventually corresponds to a simpler one with one scale less.
3. Master Integrals calculations

The SDE approach has been proven useful in calculations of MI at one and two loops.

3.1 One-loop pentagon at $O(\epsilon)$

The one-loop pentagon presented in Fig. 1 is given by

$$G_{11111} = \frac{1}{i\pi^{d/2}} \frac{1}{(-k^2)(-(k+xp_1)^2)(-(k+p_{123})^2)(-(k+p_{1234})^2)} \int d^d k$$

(3.1)

with $p_i^2 = 0$, $i = 1, \ldots, 4,$ the obvious notation $p_{i\ldots j} = p_i + \ldots + p_j$ and $p_{1234}^2 = (-p_5)^2 = 0$. The DE for the 5-point MI involves the following set of MI: four four-point $G_{11110}, G_{11101}, G_{11011}, G_{10111}$, one three-point, $G_{10110}$ and three two-point MI, $G_{00110}, G_{10010}, G_{10100}$. The two-point MI are known in a closed form in $\epsilon$. All boundary conditions have been calculated by the DE, as described in [33]. The result for the one-mass pentagon up to order $\epsilon$, is given by

$$G_{11111}(x) = \frac{c^\Gamma}{x^2 s_{23}s_{34}s_{45}} \left( 1 - \frac{1}{r_1} \right) \left( 1 - \frac{1}{r_2} \right) \left( 1 - \frac{x}{r_1} \right)^{-1-\epsilon} \left( 1 - \frac{x}{r_2} \right)^{-1-\epsilon} \sum_{i=-2}^{1} \epsilon^i f_i$$

(3.2)

where the quantities $r_1, r_2, c^\Gamma$ and $f_i$ can be found in [33]. Taking the limit $x \to 1$ from the previous expression, we get the result for the on-shell pentagon up to order $\epsilon$, that is given by

$$G_{11111}(1) = \frac{c^\Gamma}{s_{12}s_{23}s_{34}s_{45}s_{51}} \sum_{i=-2}^{1} \epsilon^i f_i$$

(3.3)

where again the $f_i$ can be found in [33].

3.2 Full set of massless double-box MI with two off-shell legs

There are in total six families of MI whose members with the maximum amount of denominators are graphically shown in Fig. 2 and Fig. 3. Three of these, Fig. 2, contain only planar MI and will therefore be referred to as the planar families. They will be denoted by $P_{12}, P_{13}$ and $P_{23}$ [36] and contain 31, 29 and 28 MI respectively. The other three families, shown in Fig. 3, contain planar MI with up to 6 denominators as well as non-planar MI with 6 and 7 denominators and will be referred to as the non-planar families of MI. These non-planar families will be denoted by $N_{12}, N_{13}$.
SecDec results have been compared with those provided by the numerical code calculations. We have performed several numerical checks of all our calculations. The numerical and numerical and \( N \) incoming.

\[ \int d^d k_1 \frac{d^d k_2}{i \pi^d/2} \frac{1}{k_1^{2\alpha_i}(k_1 + xp_1)^{2\alpha_i}(k_1 + p_{123})^{2\alpha_i}}, \]

(3.4)

where the letters appearing as weights in GPs are given by

\[
I(P_{12}) = \left\{ 0, 1, \frac{q}{s_{12}}, \frac{s_{12}}{q-s_{23}}, \frac{q-s_{23}}{s_{12}}, 1, 1 + \frac{s_{23}}{s_{12}}, \frac{s_{12}}{s_{12}+s_{23}} \right\}
\]

with \( s_{12} := p_{12}^2, s_{23} := p_{23}^2, q := p_{123}^2, p_i^2 = 0 \). Details of the calculations as well as the results in terms of GPs for all families can be found in [34].

In order to compute the MI in arbitrary kinematics, especially in the physical region, the GPs have to be properly analytically continued. In general all variables, including the momenta invariants \( s_{ij} \) (\( s_{12}, s_{23} \) and \( q \) in the present study) and the parameter \( x \), would acquire an infinitesimal imaginary part, \( s_{ij} \rightarrow s_{ij} + i \delta_{ij} \eta, x \rightarrow x + i \delta \eta \), with \( \eta \rightarrow 0 \). The parameters \( \delta_{ij} \) and \( \delta \) are determined as follows: the first class of constraints on the above-mentioned parameters originates form the input data to the DE, namely the one-scale master integrals that need to be properly defined in each kinematical region. The second class of constraints results from the second graph polynomial [40], \( \mathcal{F} \), which after expressed in terms of \( s_{ij} \) and \( x \), should acquire a definite-negative imaginary part in the limit \( \eta \rightarrow 0 \). Combining these two classes of constraints on the parameters \( \delta_{ij} \) and \( \delta \), the imaginary part of all the GPs involved is fixed and we have checked that the result for the MI is identical in the limit \( \eta \rightarrow 0 \) and moreover agrees with the one obtained by other calculations. We have performed several numerical checks of all our calculations. The numerical results have been compared with those provided by the numerical code SecDec [41, 42, 43] in the
Simplified Differential Equations Approach for Master Integrals

Costas G. Papadopoulos

3.3 Massless pentabox MI with up to one off-shell leg

For the massless pentabox MI with one off-shell leg, there are in total three families of planar MI whose members with the maximum amount of denominators, namely eight, are graphically shown in Fig.4. Similarly, there are five non-planar families of MI as given in Fig.5. We have checked that the other five-point integrals with one massive external leg are reducible to MI in one of these eight MI families. The two-loop planar and non-planar diagrams have not been calculated yet; in [35] we have recently completed the calculation of the \( P_1 \) family (Fig.4). In fact by taking the limit \( x \to 1 \) all planar graphs for massless on-shell external momenta have been derived as well.

We have used the \( \text{C++} \) implementation of the program FIRE [45] to perform the IBP reduction to the set of MI in \( P_1 \). For the family of integrals \( P_1 \) the external momenta are parametrized in \( x \) as shown in Fig.6. The parametrization is chosen such that the double box MI with two massive external legs that is contained in the family \( P_1 \) has exactly the same parametrization as that one chosen in [34], i.e. two massless external momenta \( xp_1 \) and \( xp_2 \) and two massive external momenta \( p_{123} - xp_{12} \) and \( -p_{123} \). The MI in the family \( P_1 \) are therefore a function of a parameter \( x \) and the following five invariants:

\[
s_{12} := p_{12}^2, s_{23} := p_{23}^2, s_{34} := p_{34}^2, s_{45} := p_{45}^2 = p_{123}^2, s_{54} := p_{54}^2 = p_{234}^2, p_5 := 0,
\]

where the notation \( p_{i\cdots j} = p_i + \cdots + p_j \) is used and \( p_5 := -p_{1234} \). As the parameter \( x \to 1 \), the external momentum \( q_3 := p_{123} - xp_{12} \) becomes massless, such that our parametrization also captures the on-shell case.

The resulting differential equation in matrix form can be written as

\[
\partial_x G = M \left( \{s_{ij}\}, \varepsilon, x \right) G
\]

\( 1 \)Results related to massless planar pentabox appear also recently in [44].
where $G$ stands for the array of the 74 MI involved in the family $P_i$. The twenty letters $l_i$ involved, are given in [35]. Although the DE can be solved starting from, e.g. (3.5), and the result can be expressed as a sum of GPs with argument $x$ and weights given by the letters $l_i$, it is more elegant and easy-to-solve to derive a Fuchsian system of equations \[ \partial_x G = \left( \varepsilon \sum_{i=1}^{19} \frac{M_i}{(x - l_i)} \right) G \] (3.6)

where the residue matrices $M_i$ are independent of $x$ and $\varepsilon$. The result can be straightforwardly given as

$$G = \varepsilon^{-2} b_0^{(-2)} + \varepsilon^{-1} \left( \sum_{a=0}^{19} \mathcal{G}_a M_a b_0^{(-2)} + b_0^{(-1)} \right) + \left( \sum_{ab} \mathcal{G}_{ab} M_a M_b b_0^{(-2)} + \sum_{a} \mathcal{G}_a M_a b_0^{(-1)} + b_0^{(0)} \right)$$

+ $\varepsilon \left( \sum_{abcd} \mathcal{G}_{abcd} M_a M_b M_c M_d b_0^{(-2)} + \sum_{abc} \mathcal{G}_{abc} M_a M_b M_c b_0^{(-1)} + \sum_{ab} \mathcal{G}_{ab} M_a M_b b_0^{(0)} + \sum \mathcal{G}_a M_a b_0^{(1)} + b_0^{(2)} \right)$

with the arrays $b_0^{(k)}$, $k = -2, \ldots, 2$ representing the $x$-independent boundary terms in the limit $x = 0$ at order $\varepsilon^k$. The expression is in terms of Goncharov polylogarithms, $\mathcal{G}_{ab\ldots} = \mathcal{G}(l_a, l_b, \ldots; x)$. Details on the calculation of boundary terms and of the $x \to 1$ limit can be found in [35].

The solution for all 74 MI contains $O(3,000)$ GPs which is roughly six times more than the corresponding double-box with two off-shell legs planar MI. We have performed several numerical checks of all our calculations. The numerical results, also included in the ancillary files [47], have been performed with the GiNaC library [48] and compared with those provided by the numerical code SecDec [41, 42, 43, 49] in the Euclidean region for all MI and in the physical region whenever possible (due to CPU time limitations in using SecDec) and found perfect agreement. For the physical region we are using the analytic continuation as described in the previous section as well as in [34]. At the present stage we are not setting a fully-fledged numerical implementation, which will be done when all families will be computed. Our experience with double-box computations show that using for instance HyperInt [50] to bring all GPs in their range of convergence, before evaluating them numerically by GiNaC, increases efficiency by two orders of magnitude. Moreover expressing GPs in terms of classical polylogarithms and Li$_{2,2}$ could also reduce substantially the CPU time [51]. Based on the above we estimate that a target of $O(10^2 - 10^3)$ milliseconds can be achieved.

4. Outlook

We have demonstrated that based on the Simplified Differential Equations approach [33] Master Integrals, including massless double-box with two off-shell legs and pentabox with up to one off-shell leg, can...
be expressed in terms of Goncharov polylogarithms. The complexity of the resulting expressions is certainly promising that the project of computing all MI relevant to massless QCD, namely all eight-denominator MI with arbitrary configuration of the external momenta, is feasible. Having such a complete library of two-loop MI, the analog of $A_0, B_0, C_0, D_0$ scalar integrals at one loop, the reduction of an arbitrary two-loop amplitude à la OPP can pave the road for a NNLO automation in the near future.

As experience shows, there are several issues that will need to attract our attention in order to accomplish our goal. First of all in order to systematize the whole procedure of reducing an arbitrary Feynman Integral in terms of MI in an efficient way, a deepening of our current understanding of IBP identities [52, 53] is necessary [54]. Secondly, further standardising the procedure to obtain a canonical form of DE [55], which drastically simplifies the expression of MI in terms of GPs, is certainly a very desirable feature. Thirdly, the inclusion of MI with massive internal propagators, at a first stage with one mass scale corresponding to the heavy top quark, will provide the complete basis for NNLO QCD automated computations. Moreover, the calculation of boundary terms for the DE can benefit from further developments and exploitations of expansion-by-regions techniques, in conjunction with Mellin-Barnes representation of the resulting integrals. Finally, on the numerical side, a more efficient $^3$ computation of polylogarithms is also necessary.
