Abstract

We employ the twistor approach to the construction of U(2) multi-instantons à la \'{t}Hooft on noncommutative $\mathbb{R}^4$. The noncommutative deformation of the Corrigan-Fairlie-\'{t}Hooft-Wilczek ansatz is derived. However, naïvely substituting it into the \'{t}Hooft-type solution is unsatisfactory because the resulting gauge field fails to be self-dual on a nine-dimensional subspace of the Fock space. We repair this deficiency by a suitable Murray-von Neumann transformation after a specific projection of the gauge potential. The proper noncommutative \'{t}Hooft multi-instanton field strength is given explicitly, in a singular as well as in a regular gauge.

Introduction and results

It is plausible that at very small scales space-time coordinates are to be replaced by some noncommutative structure. In order to realize this idea it is necessary to merge the framework of gauge field theory with the concepts of noncommutative geometry [1,2,3].

The dynamics of nonabelian gauge fields involves configurations not accessible by perturbation theory, in which instantons are the most prominent (in Euclidean space-time). In order to describe the nonperturbative structure of noncommutative gauge theory, it is therefore mandatory to construct the noncommutative deformation of the notion of instanton con-figurations.

The first examples of noncommutative instantons were given by Nekrasov and Schwarz [4] who modified the Atiyah-Drinfeld-Hitchin-Manin (ADHM) construction [5] to resolve the singularities of instanton moduli space (due to zero-size instantons). Furthermore, they showed that on noncommutative $\mathbb{R}^4$, nonsingular instantons exist even for the $U(1)$ gauge group. This exemplifies the observation that noncommutativity of the coordinates eliminates singular behavior of field configurations. Since then, numerous papers have been devoted to this subject (19-23), most of all employing the modified ADHM construction on noncommutative Euclidean space-time. Other related works have appeared in (24-38).

In the present paper, we focus on the noncommutative generalization of 't Hooft's multi-instanton configurations for the $U(2)$ gauge group. Nekrasov and Schwarz [4] proposed to keep the form of the 't Hooft solutions of the (commutative) self-duality equations but imply noncommutativity on the coordinates. This naive noncommutative 't Hooft con-figuration suffers from a problem, however. As was discovered by Corrigan et al. [25] for the spherically-symmetric one-instanton configuration, the Yang-Mills field fails to be self-dual everywhere. Technically, the deficiency originates from a source term in the equation for the scalar field in the Corrigan-Fairlie-'t Hooft-Wilczek (CFtHW) ansatz. Here, we generalize the result of [25] to the naive noncommutative multi-instanton configurations by deriving their source term and discuss the singular nature of the ansatz. For comparison, we outline the ADHM derivation of the field strength in an Appendix.

In the commutative case, in contrast, such source term is absent because the singularities of 2 are cancelled by the zeros of $\frac{1}{r}$. Yet, singularities are present in the gauge potential. However, it is well known how to remove such singularities by a singular gauge transformation, producing for example the Belavin-Polyakov-Schwarz-Tyupkin (BPST) instanton. Therefore, one may wonder if a noncommutative analogue exists which removes the source term and thus yields a completely regular noncommutative multi-instanton whose field strength is self-dual everywhere.

In the present paper, we answer this question in the affirmative. We easily adapt the twistor approach (which in fact underlies the ADHM scheme [5]) to the noncommutative situation, by promoting functions to operators acting on a harmonic-oscillator Fock space. Employing the simplest Atiyah-Ward ansatz for the matrix-valued function of the associated Riemann-Hilbert problem, we straightforwardly derive the noncommutative generalization of the CFtHW ansatz.

The shortcomings described above are remedied by projecting the naive noncommutative 't Hooft multi-instanton field strength to the source-free subspace of the Fock space and then applying to it a particular Murray-von Neumann (MvN) transformation. Such a transformation is not unitary but generalizes the known commutative singular gauge transformation and removes the troublesome source term. The gauge potential producing the projected 't Hooft multi-instanton

---

For the one-instanton configuration such a transformation was considered by Fujiuchi [7] in the ADHM approach.
gauge field cannot be obtained by the standard projection since projecting does not commute with calculating the field strength. The projected configuration may be termed the noncommutative ’t Hooft instanton in a singular gauge, but its gauge potential turns out to be given only implicitly. Nevertheless, after the MN transformation (on the projected field configuration) we obtain the correct noncommutative ’t Hooft n-instanton, which contains all known explicit solutions as special cases.

2 Instantons from the twistor approach

Definitions and notation. We consider the Euclidean space \( \mathbb{R}^4 \) with the metric \( \eta \), a gauge potential \( A = A^I dx^I \) and the Yang-Mills fields \( F = da + A^I \wedge A^J \) with components \( F^I = \delta^I_A A^I + [A^I; A^J] \), where \( \delta = \delta^x = 0 \) and \( ;;:: = 1;2;3;4 \). The fields \( A \) and \( F \) take values in the Lie algebra \( u(2) \).

The self-dual Yang-Mills (SDYM) equations have the form:

\[
F = F^* = \frac{1}{2} \varepsilon^{IJKL} F_{IJ} F_{KL} \quad (2.1)
\]

where \( \varepsilon \) denotes the Hodge star operator and \( \varepsilon^{IJKL} \) is the completely antisymmetric tensor in \( \mathbb{R}^4 \), with \( \varepsilon^{1234} = 1 \). Solutions of (2.1) having finite Yang-Mills action are called instantons. Their action

\[
S = \frac{1}{g^2} \int tr F^* F \quad (2.2)
\]

equals \( 2g^2 \) times an integer which is the topological charge

\[
Q = \frac{1}{8} \int tr F^* F \quad (2.3)
\]

By 'tr' we denote the trace over the \( u(2) \) gauge algebra and by \( g \) the Yang-Mills coupling constant hidden in the definition of the Lie algebra components of the fields \( A \) and \( F \).

If we introduce complex coordinates

\[
y = x^1 + ix^2; \quad z = x^3 + ix^4; \quad y = x^1 + ix^2; \quad z = x^3 + ix^4 \quad (2.4)
\]

and put

\[
A_y = \frac{1}{2} (A_1 \varepsilon^2); \quad A_z = \frac{1}{2} (A_3 + iA_4); \quad A_y = \frac{1}{2} (A_1 + iA_2); \quad A_z = \frac{1}{2} (A_3 - iA_4) \quad (2.5)
\]

then the SDYM equations (2.1) will read

\[
[D_y; D_z] = 0; \quad [D_y; D_z] = 0; \quad [D_y; D_y] + [D_z; D_z] = 0 \quad (2.6)
\]

where \( D := \delta + A \). These equations can be obtained as the compatibility condition of the following linear system of equations:

\[
(D_y - D_z) (x; ) = 0 \quad \text{and} \quad (D_z + D_y) (x; ) = 0 \quad (2.7)
\]

where the 2 \times 2 matrix depends on \( (y;z;z;z) \) but not on \( y \). The 'spectral parameter' lies in the extended complex plane \( \mathbb{C}P^1 = \mathbb{C} \setminus \{ f \} \).
Twistors and transition functions. In fact, the function $\text{(2.7)}$ is defined on the twistor space $P = R^4 \times CP^1$ for the space $R^4$ [39,40]. The sphere $S^2$, considered as the complex projective line $CP^1$, can be covered by two coordinate patches $U_+$ and $U$ with

$$CP^1 = U_+ \cup U; \quad U_+ = CP^1 \nfl g; \quad U = CP^1 \nfg; \quad \text{(2.8)}$$

and coordinates and ~ on $U_+$ and $U$, respectively. Therefore, also $P$ can be covered by two coordinate patches,

$$P = U_+ \cup U; \quad U_+ = R^4 \times U_+; \quad U = R^4 \times U; \quad \text{(2.9)}$$

with complex coordinates

$$w_1 = y\ z;\ w_2 = z + y;\ w_3 = \quad \text{and} \quad w_1 = ~y\ z;\ w_2 = ~z + y;\ w_3 = ~ \quad \text{(2.10)}$$

on $U_+$ and $U$, respectively. On the intersection $U_+ \setminus U \setminus R^4 C$ these coordinates are related by

$$w_1 = \frac{w_1}{w_3}; \quad w_2 = \frac{w_2}{w_3} \quad \text{and} \quad w_3 = \frac{1}{w_3}; \quad \text{(2.11)}$$

On the open set $U_+ \setminus U \setminus P$. From [2.7] it follows that $f_+$ depends on the complex coordinates $w_1, w_2$ and holomorphically,

$$(\partial_y \partial_z)f_+ = 0 \quad \text{and} \quad (\partial_z + \partial_y)f_+ = 0 \quad =) \quad f_+ = f_+ (w_1; w_2; \quad \text{(2.12)}$$

Any such function defines a holomorphic bundle over $P$. Namely, $f_+$ can be identified with a transition function in a holomorphic bundle over $P$, and a pair of functions $\Delta$ defines a smooth trivialization of this bundle.

Gauge equivalence and reality conditions. It is easy to see that gauge transformations

$$A \quad \nfl A^g = g^{-1}Ag + g^{-1}kg \quad \text{(2.14)}$$

are induced by the transformations

$$f_+ \quad \nfl g = g_1^{-1} \quad \text{and} \quad f_+ \quad g = g_1 \quad \text{(2.15)}$$

where $g = g(x)$ is an arbitrary $U(2)$-valued function on $R^4$. The transition function $f_+ = f_+^{-1}$ is invariant under these transformation. On the other hand, the gauge potential $A$ is inert under the transformations

$$f_+ \quad \nfl h_+^{-1} \quad \text{and} \quad f_+ \quad h_1 \quad \text{(2.16)}$$

where $h_+ = h_+ (w_1; w_2; \quad \text{and} \quad h = h (w_1; w_2; \text{~})$ are arbitrary matrix-valued holomorphic functions on $U_+$ and $U$, respectively.
The reality of the gauge fields is an important issue \([38, 40]\). The antisymmetry conditions \(A^Y = A\) for components of the gauge potential imply the following 'reality' conditions for the matrices and \(f_+\):

\[
y_+(x; ; )_1 = 1(x; ; )_1 \quad \text{and} \quad f_+(x; ; )_1 = f_+(x; ; )_1 ; \tag{2.17}
\]

Splitting of transition functions. Consider now the inverse situation. Let us have a holomorphic matrix-valued function \(f_+\) on the open subset \(U_+ \setminus \mathcal{U}\) of the twistor space \(\mathcal{U}\). Suppose we are able to split \(f_+\), i.e., for each fixed \(x \times 2 \mathbb{R}^4\), we define \(f_+\) on \(U_+ \setminus \mathcal{U}\) and the functions \(f_+\) and \(f_-\) can be extended continuously to functions regular on \(U_+\) and \(U\), respectively. From the holomorphicity of \(f_+\), it then follows that

\[
+ (\theta_y, \theta_z) = 1, \quad (\theta_y, \theta_z) = 1 \quad \text{and} \quad + (\theta_y + \theta_y, \theta_y) = 1 ; \tag{2.18}
\]

Recall that the matrix-valued functions \(f_+\) and \(f_-\) are regular in their respective domains, so that we may expand them into power series in \(z^i\) and \(z^\dagger\), respectively.

Upon substituting into (2.15) one easily sees that both sides of (2.18) must be linear in \(z\), and one can introduce \(A^Y\) by

\[
A^Y = A_+ + A_- \quad \text{and} \quad A_+ + A_- = \left[ \begin{array}{c} \theta_y \\ \theta_z \end{array} \right] \tag{2.19}
\]

Hence, the gauge field components may be calculated from

\[
A^Y = + \theta_y + \theta_y \quad \text{and} \quad A^Y = + \theta_z + \theta_z = A^Y \tag{2.20}
\]

By construction, the components \(A^Y\) of the gauge potential \(A\) defined by (2.15) satisfy the SDYM equations. For more detailed discussion of local solutions, their in nine-dimensional moduli space and references see e.g. \([41, 42]\).

For a fixed point \(x \times 2 \mathbb{R}^4\), the task to split a matrix-valued holomorphic function \(f_+\) or \(f_-\) is known as the partition \(R\)-linear bilinear problem on \(\mathbb{C}P^3\). The explicit general solution of this \(R\)-linear bilinear problem is not known. For a large class of special cases, however, the splitting can be achieved. In this paper we shall make explicit use of a particular example, the so-called Atiyah-Ward ansatz \([39]\), to be presented momentarily in the noncommutative context.

3 The Atiyah-Ward ansatz

Noncommutative Yang-Mills theory. The noncommutative deformation of (classical) field theory is most easily effected by extending the function product in field space to the star product

\[
(f \ast g)(x) = f(x) \exp \frac{i}{2} \theta A \theta g(x) ; \tag{3.1}
\]

with a constant antisymmetric tensor \(A\). In this work, we restrict ourselves to the case of a self-dual \((=1)\) or an anti-self-dual \((=1)\) tensor and choose coordinates such that

\[
12 = 21 = 34 = 43 = > 0 : \tag{3.2}
\]

In star-product formulation, the SDYM equations (2.3) are formally unchanged, but the components of the noncommutative field strength now read

\[
F = \theta A \theta A + \theta A = A \theta A : \tag{3.3}
\]
The non-locality of the star product renders explicit computations cumbersome. We therefore
take advantage of the Moyal-Weyl correspondence and pass to the operator formalism, which trades
the star product for operator-valued coordinates \( \hat{x} \) satisfying \( [\hat{x}; \hat{x}] = i \). This defines the
noncommutative Euclidean space \( \mathbb{R}^4 \). In complex coordinates (2.4) our choice (3.3) implies
\[
[\hat{y}; \hat{y}] = 2; \quad [\hat{z}; \hat{z}] = 2; \quad \text{and other commutators} = 0:\tag{3.4}
\]
Clearly, coordinate derivatives are now inner derivations of this algebra, i.e.
\[
\hat{\theta}_y \hat{f} = \frac{1}{\pi} [\hat{y}; \hat{f}] \quad \text{and} \quad \hat{\theta}_y \hat{f} = \frac{1}{\pi} [\hat{y}; \hat{f}]
\] for any function \( \hat{f} \) of \( (\hat{y}; \hat{y}; \hat{z}; \hat{z}) \). Analogous formulae hold for \( \hat{\theta}_z \).

The obvious representation space for the Heisenberg algebra (3.4) is the two-oscillator Fock
space \( \mathcal{H} \) spanned by \( f_{n_1 n_2} \) with \( n_1 n_2 = 0; 1; 2; \ldots \). In \( \mathcal{H} \) one can introduce an integer ordering
of states e.g. as follows [37]:
\[
\hat{\mathbf{k}} = \hat{n}_1 n_2 = \frac{\hat{y}^{n_2} \hat{n}_2 \hat{f}_{n_1 0 i}}{n_1 n_2 ![2]^{n_1+n_2}} \quad \text{with} \quad z = \frac{1}{2} \hat{z} + \frac{1}{2} \hat{\hat{z}}\tag{3.6}
\]
and \( k = n_1 + \frac{1}{2} (n_1 + n_2)(n_1 + n_2 + 1) \). Thus, coordinates as well as \( \mathbf{e}_k \)s are to be regarded as
operators in \( \mathcal{H} \). The Moyal-Weyl map yields the operator equivalent of star multiplication and
integration,
\[
z f \otimes g = \int d^4x f (2 \hat{\mathcal{T}}_{\mathfrak{H}_1} \hat{f}) \tag{3.7}
\]
respectively, where \( \hat{\mathcal{T}}_{\mathfrak{H}_1} \) signifies the trace over the Fock space \( \mathcal{H} \).

In the operator formulation, the noncommutative generalization of the SDYM equations (2.4)
again retains their familiar form,
\[
\hat{F}_{yz} = 0; \quad \hat{F}_{xy} = 0; \quad \hat{F}_{yx} + \hat{F}_{zy} = 0:\tag{3.8}
\]
The operator-valued \( \mathbf{e}_k \)-strength components \( \hat{F} \), however, now relate to the noncommutative
gauge-potential components \( \hat{A} \) with the help of (3.3), as e.g. in
\[
2 \hat{F}_{yz} = [\hat{y} + \hat{A}_y; \hat{A}_z] = [\hat{z} + \hat{A}_z; \hat{A}_y]:\tag{3.9}
\]
For the rest of the paper we shall work in the operator formalism and drop the hats over the
operators in order to avoid cluttering the notation.

On noncommutative Atiyah-Ward ansätze. Commutative instantons can be obtained by the fam-
ous ADHM construction [11], which was derived from the twistor approach. Almost all works on
noncommutative instantons are based on the modified ADHM construction [23]. At the same time,
short of results it is known that the modified ADHM construction can be interpreted terms of a noncom-
mutable version of the twistor transform [23, 24], Therefore it is reasonable to expect that an
approach based on the splitting of transition functions in a holomorphic bundle over a noncommu-
tative twistor space [23, 24, 25] will work as well. Here we show that this is indeed the case for the
simplest Atiyah-Ward ansätze for the transition functions.

In the commutative situation the infinite hierarchy of Atiyah-Ward ansätze reads
\[
f^{(k)}_+ = \begin{pmatrix} 0 \\ k \end{pmatrix} \tag{3.10}
\]
where \( k = 1, 2; \ldots \) and \( \Phi \) denotes a holomorphic function on \( \mathbb{U}_+ \). We are confident that the ansatz \( (3.10) \) allows one to construct solutions of the noncommutative SDYM equations \( (2.22) \) simply by promoting \( \Theta \) to an operator acting in the Fock space \( \mathbb{H} \).

Specializing to \( k = 1 \), we introduce the matrix

\[
f_+ = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad f_+^{(1)} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.
\]

Because \( f_+ \) is related to \( f_+^{(1)} \) by a transformation \( (2.14) \), with \( h_+ = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \) and \( h = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \), it leads to the same gauge field configuration. Yet, \( f_+ \) has the advantage of satisfying the reality condition \( (2.17) \). Here \( \Phi \) is a holomorphic `real' operator-valued function, i.e.

\[
(\Theta_y \quad \Theta_z) = (\Theta_z + \Theta_y) = 0 \quad \text{and} \quad \Theta(x; \; 1) = (x; 1).
\]

It is useful to expand \( \Phi \) in a Laurent series in \( \Theta \),

\[
\Phi^m \Theta^m = + + \; ;
\]

where

\[
\Phi^m = X \quad \text{and} \quad \Theta^m = 0.
\]

The reality condition \( (2.17) \) then becomes

\[
\Theta(x) = (x) \quad \text{and} \quad \Theta(x; \; 1) = (x; 1).
\]

It is not difficult to see that \( f_+ \) can be split as \( f_+ = f_+^{(1)} \), where

\[
1 = \frac{1}{1} + \frac{1}{1} \quad \text{and} \quad 1 = + + 1.
\]

Consequently, we have

\[
1 = 1 + 1 + 1 \quad \text{and} \quad + = 1 + 1 + 1.
\]

which satisfy the reality condition \( (2.17) \). Thus, the first Atiyah-Ward ansatz is easily generalized to the noncommutative case.

Parametrization of the gauge potential. From the operator version of formulae \( (2.13) \) and recursion relations

\[
\Theta_{y,m+1} = \Theta_{z,m} \quad \text{and} \quad \Theta_{z,m+1} = \Theta_{y,m}
\]

\[2\] A reminder on the commutative situation: For \( k = 1 \), the ansatz \( (3.10) \) leads to a parametrization of selfdual gauge fields of a scalar field \( \Phi = \text{res}_- \left( \begin{pmatrix} 1 \\ 0 \end{pmatrix} \right) \) satisfying the wave equation, while for \( k \geq 2 \) it produces solutions more general than the \( \Phi \)-Hoffmann-instanton configurations \( [38, 43, 44, 45] \). Note that the matrices \( f_+^{(1)} \) do not satisfy the reality condition \( (2.17) \).
implies by (3.12) for the Laurent coefficients in (3.13) we get

\[
\begin{align*}
A_y &= \frac{1}{2} \theta_0 \frac{1}{z} \frac{1}{z} \frac{1}{z} (\theta_z) \frac{1}{z} \theta_y \frac{1}{z} ; \\
A_z &= \frac{1}{2} \theta_0 \frac{1}{z} \frac{1}{z} \frac{1}{z} (\theta_z) \frac{1}{z} \theta_y \frac{1}{z} ; \\
A_L &= \frac{1}{2} \theta_0 \frac{1}{z} \frac{1}{z} \frac{1}{z} (\theta_z) \frac{1}{z} \theta_y \frac{1}{z} ; \\
A_L &= \frac{1}{2} \theta_0 \frac{1}{z} \frac{1}{z} \frac{1}{z} (\theta_z) \frac{1}{z} \theta_y \frac{1}{z} ; \quad \text{(3.19)}
\end{align*}
\]

Rewriting these expressions in real coordinates \(x\), we obtain the noncommutative generalization of the CFH\text{\textsuperscript{T}}W ansatz,

\[
A = a \frac{a}{2} \left[ \frac{1}{z} \theta_0 \frac{1}{z} \frac{1}{z} \theta_0 + \frac{1}{2} \frac{1}{z} \theta_0 + \frac{1}{z} \theta_0 \right] ; \quad \text{(3.20)}
\]

where

\[
\begin{align*}
8 & \rightarrow \text{ for } a = b ; c = c \\
8 & \rightarrow \text{ for } a = 4 \\
8 & \rightarrow \text{ for } a = 4
\end{align*}
\]

is the anti-self-dual 't Hooft tensor \[^{44}\text{]}\), and

\[
1 = 0 \quad 0 \quad 1 \\
1 = 0 \quad i \quad 0 \\
3 = 0 \quad 0 \quad 1
\]

are the Pauli matrices.

Reduced SDYM equation. Calculating the Yang-Mills curvature for the noncommutative CFH\text{\textsuperscript{T}}W ansatz (3.20) results in

\[
F_{yz} = 0 \quad X \quad 0 \quad 0 ; \\
F_{yz} = 0 \quad X \quad 0 \quad 0 ; \\
F_{yy} + F_{zz} = X \quad 0 \quad 0
\]

with

\[
X = \frac{1}{2} \theta_0 \theta_0 + \theta_z \theta_z
\]

Hence, for the ansatz (3.20) the noncommutative SDYM equations (3.2) are reduced to

\[
\frac{1}{2} (\theta_0 \theta_0 + \theta_z \theta_z) \frac{1}{z} = 0
\]

It is natural to assume \[^{6}\text{]}\) that a solution \(n\) of this equation looks exactly like the standard 't Hooft solution

\[
n = 1 + \sum_{i=1}^{\infty} \frac{2}{(x b_1)} \left( \frac{1}{x b_1} \right) = 1 + \sum_{i=1}^{\infty} \frac{2}{x b_1} ;
\]

where now the \(x\) are operators and

\[
\frac{1}{x} = \frac{1}{2} \left( \frac{x}{n_1 n_2} \right) \frac{1}{n_1 + n_2 + 1} \; j_{n_1 n_2} ; j_{n_1 n_2 j} ;
\]

where
\[ r_1^2 = (x - b_1)(x - b_1) = y_1y_1 + z_1z_1 = y_1y_1 + z_1z_1 + 2 ; \]
\[ y_1 = y - b_1^2 ; z_1 = z - b_1^2 ; b_1 = (b_1) = (b_1^2, b_1^2) ; b_i = (b_i) = (b_i^2, b_i^2) ; \]
\[ \text{where} \quad r^2 = xx = \frac{1}{2}(yy + yy + zz + zz) = yy + zz = yy + zz + 2 ; \]

The real parameters \( b_1 \) and \( b_i \) denote the position coordinates and the scale of the \( i \)th instanton. In particular, as a candidate for the one-instanton solution we have (putting \( b_2 = 0 \))
\[ \frac{1}{r^2} = 1 + \frac{2}{x^2} ; \]

The real parameters \( b_1 \) and \( b_i \) denote the position coordinates and the scale of the \( i \)th instanton. In particular, as a candidate for the one-instanton solution we have (putting \( b_2 = 0 \))
\[ \frac{1}{r^2} = 1 + \frac{2}{x^2} ; \]

\[ \text{Sources. When checking the self-duality of the purported one-instanton configuration one discovers a subtlety: The substitution of (3.23) into the reduced SDYM equation (3.24) and results [43] on Green's functions reveals that the deviation from self-duality,} \]
\[ X_1 = \frac{1}{2} \left( \Theta_y \Theta_y n + \Theta_z \Theta_z n \right) = \frac{1}{2} \left( n + 2 \right) P_0 \quad \text{with} \quad P_0 = \epsilon y; 0i; 0j ; \]

\[ \text{is not zero if} \quad b \in 0. \text{This has led the authors of [41] to the conclusion that this configuration is not self-dual. This is not the whole story - one can show that all \( n \) in (3.24) fail to satisfy (3.25). Namely, by differentiating we obtain} \]
\[ \Theta_y \Theta_y n + \Theta_z \Theta_z n = \frac{1}{4} X^n \sum_{i=1}^{2} b_i^2 \epsilon y; i ; b_i^2 \epsilon y; j ; \]

\[ \text{where} \quad \epsilon y; i = \epsilon y; b_i^2 i = e^{\frac{1}{2} b_i^2} e^{y; b_i^2} e^{y; b_i^2} e^{y; b_i^2} = \frac{1}{2} \epsilon y; 0i \]

\[ \text{denotes the 'shifted ground state' centered at \( b_1 \) which is constructed as a coherent state for the} \]
\[ \text{Heisenberg-Weyl group generated by the algebra (3.4). The vectors} \quad f h_1^1; \ldots; h_n^i \quad \text{of this subspace through} \quad [43] \]
\[ f h_1^1; h_2^1; \ldots; h_n^i = T(T^*T)^{\frac{1}{2}} \quad \text{with} \quad T = f h_1^1; h_2^1; \ldots; h_n^i ; \]

\[ \text{This basis can be extended to an orthonormal basis of the whole Fock space \( H \) by simply adjoining further vectors} \quad f h_{n+1}^1; f h_{n+2}^1; \ldots; \quad \text{From the explicit form of the function} \quad n \quad \text{it follows that the} \]
\[ \text{matrix elements} \quad h_i h_j n \quad \text{are nonzero only for} \quad i; j \quad \text{and} \quad n. \text{Therefore, the operator} \quad n \quad \text{preserves the subspace of} \quad H \quad \text{spanned by the vectors} \quad f h_i^1; i = 1; \ldots; n, \text{i.e.} \]
\[ n \quad f h_i^1 = \frac{X^n}{X^n} \quad \text{and} \quad h_i h_j n \quad f h_i^1 = \frac{X^n}{X^n} \quad h_i h_j n \quad f h_i^1 \]

\[ \text{where} \quad M_{ij} = M_{ij} \quad (i; j; \ldots; 2 \quad n) \quad \text{are some constants. Using this fact we arrive at} \]
\[ X_n = \frac{1}{n} \left( \Theta_y \Theta_y n + \Theta_z \Theta_z n \right) n \quad \frac{1}{2} \quad \frac{1}{2} \quad X^n \quad f h_i^1 M_{ki} \quad f h_j^1 M_{ki} \quad f h_j^1 M_{ki} \quad f h_j^1 M_{ki} \quad f h_j^1 M_{ki} \quad f h_j^1 M_{ki} ; \]

\[ \text{which is not zero if at least one} \quad \frac{1}{2} \quad \text{does not vanish. The Appendix derives the same expression via the ADHM approach.} \]
4 Noncommutative instantons

Projected field configurations. The twistor approach has given us a systematic way of producing a noncommutative generalization (3.20) of the CFHW ansatz. However, it has been shown above that the noncommutative ‘t Hooft type ansatz (3.22) does not solve the SDYM equations since \( X_n \neq 0 \) produce sources in the r.h.s. of (3.22). These sources are localized on a nine-dimensional subspace of the Fock space.

Let us look at the situation in more detail. Recall that in the noncommutative case the components \( A \) and \( F \) are operators acting (on the left) in the space \( H = C^2 = H \otimes H \) which carries a fundamental representation of the group \( U(2) \). It is easy to see that for the ansatz (3.22) each term of the operators \( A \) in (3.20) annihilates the state \( j_P;0_i \) \( C^2 \) or \( C^2 \) \( h_P;0_j \) (when acting on the right), \( h_P;0_j A_j P;0_i = 0 \). This shows that the \( A \) are well defined only on the subspace \( (1 P_0)H \bigotimes C^2 \) of the Fock space. Moreover, from (3.33) we see that the gauge fields are self-dual only on the same subspace since \( X_1(1 P_0) = 0 \). Analogously, one can easily see that \( X_n \) given by (3.23) is annihilated by the projector

\[
1 \quad P_n \quad 1 = \begin{pmatrix} X^0_{ij} & 1 \\ 1 & H \end{pmatrix} \quad H \quad 1 = \begin{pmatrix} X^0_{ij} & 1 \\ 1 & H \end{pmatrix} H H \quad 1 \quad (4.1)
\]

onto the orthogonal complement of the subspace spanned by \( f \beta_i;i = 1;\cdots;n \) but not outside it. Therefore, the solutions based on (3.23) are self-dual on the reduced Fock space \( (1 P_n)H \bigotimes C^2 \) (projective Fock module). The same phenomenon occurs in the modified ADHM construction of the noncommutative one- and two-instanton solutions and was discussed intensively by Fox \([6]\) and especially by Furuchi \([7,8,9,10,11]\). The ADHM construction of noncommutative ‘t Hooft \( n \)-instantons including the appearance of a source term for any \( n \) is described in the Appendix. Note that the deletion of a subspace generated by \( n \) states \( f \beta_i;i = 1;\cdots;n \); from the Fock space corresponds to the exclusion of \( n \) points \( h_P;i = 1;\cdots;n \); (in which the gauge potential is singular) from the commutative space \( R^4 \). Hence, the sources in the r.h.s. of (3.22), being localized on the subspace \( P_n H \bigotimes C^2 \), imply that the ansatz (3.23) produces a singular solution.

Quite generally, consider any nine-rank projector \( P \). If the deviation from self-duality is localized on the subspace \( P H \bigotimes C^2 \) of the Fock space then obviously we can produce a self-dual field strength \( F^P \) by projecting the gauge field onto the reduced Fock space \( (1 P)H \bigotimes C^2 \),

\[
F \quad T \quad F^P = (1 P) F \quad (1 P) : \quad (4.2)
\]

Unfortunately, the corresponding gauge potential \( A^P \) generating this \( F^P \) cannot be obtained by naively projecting \( A \), since projecting does not commute with calculating the field strength:

\[
A \quad ' \quad F \quad \gamma \quad \gamma \\
A \quad ' \quad F \quad \gamma \quad \gamma
\]

\[
A^P \quad ' \quad F^P
\]

where \( # \quad P \) denotes the standard projection onto \( (1 P)H \bigotimes C^2 \) and \( _p \) compute the curvature in the full and the reduced Fock space, respectively. More explicitly, it reads

\[
F = \partial(A) + [A;A];
\]

\[
F^P = (1 P) \partial(A) \quad (1 P) + [A^P;A^P] + (1 P) \partial(A) \quad (1 P) ; \quad (4.3)
\]
Although $A^\rho$ is a projected gauge potential, i.e. it fills

$$A^\rho = (1 \ P) A^\rho (1 \ P) ;$$  \hspace{1cm} (4.4)

a short calculation reveals that it differs from the standard projection of $A$ \(^\dagger\).

To avoid confusion, we call $A^\rho$ the 'projected' gauge potential. As the question mark in the above diagram indicates, it is given only in implicit as a function of $A$ through

$$(1 \ P ) \theta [ A^\rho + [ A \ ; A ] \ ] = (1 \ P ) ( \theta [ A^\rho ] + [ A^\rho ; A^\rho ] + \theta [ \ P \ ; \ P ] ) (1 \ P ) ;$$  \hspace{1cm} (4.5)

Similarly to the question of deriving some gauge potential $A$ from a given field strength $F$ in ordinary Yang-Mills theory, it seems difficult to assert the existence of $A^\rho$ solving (4.5) for a given $A$. Our analogue of the Bianchi identity are the necessary conditions

$$(1 \ P ) \theta [ F^\rho P = F^\rho \ ; P ] \quad \text{and} \quad (1 \ P ) \theta [ F^\rho P (1 \ P ) = F^\rho \ ; A^\rho ] ;$$  \hspace{1cm} (4.6)

of which the first one is solved by (4.4) but the second one is nontrivial. Nevertheless, from the existence of the canonical solution $A^\rho = A$ for $\rho = 0$ and the smoothness of all expressions in the deformation parameter, we derive some confidence that $A^\rho$ should exist at least for sufficiently small values of $\rho$.

Murray-von Neumann transformations. After projecting our gauge field $F \mapsto F^\rho$ via (4.4) and finding a solution $A^\rho$ of (4.5), we obtain a self-dual configuration $(A^\rho; F^\rho)$ which may be termed the noncommutative four-dimensional multi-instanton $(A^\rho; F^\rho)$ in a singular gauge. As is well known in the commutative situation (see e.g. [3]), the singularity in the gauge potential can be removed by a singular gauge transformation, leading for instance to the BPST form of the one-instanton solution. The noncommutative analogues of such singular gauge transformations are so-called Murray-von Neumann (MVN) transformations. Indeed, such transformations were proposed in a different context (the odder ADHM approach) to remove the singularity of the noncommutative one-instanton solution for the $U(1)$ and $U(2)$ gauge groups. Here we will show that also for the noncommutative four-dimensional solutions there exist MVN transformations which, in combination with suitable projections, repair the deficiency in (3.35) and produce regular solutions for any finite $N$.

Given our nine-rank projector $P$, we consider a special kind of MVN transformations (partial isometry $[3])$,

$$A^\rho \mapsto A^0 = V^\rho A^\rho V + V^\rho \theta [ V ] \quad \text{and} \quad F^\rho \mapsto F^0 = V^\rho F^\rho V ;$$  \hspace{1cm} (4.7)

where the intertwining operators

$$V: H \to C^2 \ \quad \text{and} \quad V^\rho: (1 \ P) H \to C^2 \ \quad \text{and} \quad V^\rho: (1 \ P) H \to C^2$$  \hspace{1cm} (4.8)

satisfy the relation

$$V^\rho V = 1 \ \quad \text{while} \quad V V^\rho = 1 \ P$$  \hspace{1cm} (4.9)

upon extension to $H \to C^2$. The configuration $(A^\rho; F^\rho)$ lives on the projective Fock module $(1 \ P) H \to C^2$, but $(A^0; F^0)$ exists on the free Fock module $H \to C^2$. Therefore, the gauge fields are related to their potentials by (4.3) and

$$F^0 = \theta [ A^0 ] + [ A^0 \ ; A^0 ] ;$$  \hspace{1cm} (4.10)

\[3\] In a previous version of the paper we erroneously identified $A^\rho$ with $(1 \ P) A (1 \ P)$. We thank Diego Correa and F Hel Schaposnik for questions which expose this confusion to us.

\[4\] O.L. thanks Martin Rocek for a discussion on this point.
Via the natural embedding of the reduced Fock space into the full Fock space, we may extend $V$ and $V^\dagger$ to endomorphisms of $H = \mathbb{C}^2$ by declaring $V^\dagger P = 0 = VP$. Although the extended $V$ is not unitary, the transformations (4.13) can be regarded as a noncommutative version of singular gauge transformations. Furthermore, we may actually bypass the projection as far as the field strength is concerned and directly compute

$$F^0 = V^\dagger F V \quad (4.11)$$

In the following subsections we will demonstrate that to the singular configuration (5.20) with $V$ from (3.26) one should apply first a projection onto the reduced Fock space $(1\ P_0)H = \mathbb{C}^2$ to obtain the noncommutative 't Hooft multi-instanton in a singular gauge, and secondly an M vN transformation to arrive at the nonsingular noncommutative 't Hooft $n$-instanton solution. In short,

$$\begin{pmatrix} A^P & F^P \end{pmatrix} \to \begin{pmatrix} A^P & F^P \end{pmatrix} \sim V^\dagger \begin{pmatrix} A^0 & F^0 \end{pmatrix} \quad (4.12)$$

will bring us to a satisfactory instanton configuration. However, we will not be able to present explicit expressions for $A^P$ or $A^0$.

One-instanton solution. Let us consider first the one-instanton configuration (5.28) in (5.20), project it onto $(1\ P_0)H = \mathbb{C}^2$, and construct its M vN transformation matrix $V_1$. Due to the relation $(1\ P_0)X_1(1\ P_0) = 0$, the projected field strength

$$F^P = (1\ P_0)F \quad (4.13)$$

is obviously self-dual, but it is singular because ill-defined on $\mathbb{C}$. As already mentioned, we cannot rigorously prove the existence of the 'projected' gauge potential $A^P$ via (4.13) but we shall assume it henceforth.

As will be justified below, the subsequent M vN transformation applied to $(A^P;F^P)$ is conveniently factorized as $V_1 = S_1 U_1$, with

$$\begin{pmatrix} 1 & 0 \\ 0 & S_1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} z & y & i \\ y & z & r \end{pmatrix} \quad \text{where} \quad S_1 Y S_1 = 1 \quad \text{while} \quad S_1 S_1^Y = 1 \quad P_0 : \quad (4.14)$$

These relations are satisfied by the shift operator

$$S_1 = \begin{pmatrix} X \\ k \end{pmatrix} 1 + 1i-kj \quad (4.16)$$

constructed from the integer ordered states (3.4). Another possible realization of $S_1$ is

$$S_1 = 1 + \begin{pmatrix} f_0; n_2 + 1i-n_0; n_2 j \\ n_2 \end{pmatrix} f_0; n_2 i-n_0; n_2 j \quad (4.17)$$

A third possible choice (which we shall use) is a 'mixture' of (4.16) and (4.17). Namely, recall that the index $k$ in (3.4) introduces an integer ordering of states in the two-oscillator Fock space $H$:

$$k_i = f_0; 0i; f_0; 1i; f_0; 2i; \ldots \quad (4.18)$$
For fixed instanton number $n > 1$ let us move the states $j_0i;j_1i;\ldots ;j_n;i_1i;\ldots$ to the left and enumerate this new order by $k$,

$$j_0i = j_0;0i;j_1i;\ldots ;j_n;i_1i;\ldots . \quad (4.19)$$

Then, the shift operator

$$S_1 = \frac{X}{k_0} \ j + 1 \ i j \ k \ j$$

with the new ordering of states will also satisfy (4.15).

We will now confirm our claim that

$$A^0 = V_1^y A^p V_1 + V_1^y \partial V_1 \quad \text{and} \quad F^0 = V_1^y F^p V_1 \ V_1^y F \ V \quad (4.21)$$

brings us to the nonsingular noncommutative one-instanton solution. With the help of the definitions (cf. [9])

$$r_0 \ = \ r^2 \ \varepsilon \ \frac{1}{2} = \ y y + z z \ \varepsilon \ \frac{1}{2} \quad \text{and}$$

$$r_1 \ = \ (1 - P_0) \ y y + z z \ \varepsilon \ \frac{1}{2} (1 - P_0) = \ \frac{1}{P_0} \ \frac{X}{n_1;0;0} \ \frac{n_1 n_2 i n_1 n_2 j}{n_1 + n_2} \quad (4.22)$$

it is readily checked that

$$V^y_1 V_1 = 1 \ \bar{1}_2 \quad \text{but} \quad V_1 V_1^y = \frac{1}{0} P_0 \ 0 \ = \ (1 - P_0) \ 1_2; \quad (4.23)$$

Furthemore, one finds that

$$X_1 V_1 = \frac{2}{2 \ (2 + 2)} P_0 V_1 = 0 ; \quad (4.24)$$

which assures that the anti-self-dual part of $F^0$, being proportional to $V^y_1 A^p V_1$, vanishes. We emphasize that the projection $F^y$ is not used explicitly in this computation but nevertheless required if we want $F^0$ to come from a gauge potential $A^0$ which derives from $A^p$ by an MvN transformation.

Obviously, the MvN transformation (4.21) extends the self-duality of $F^p$ to the whole Fock space $H_C^2$. This is exactly what was desired to cure the incompleteness of the configuration (3.20) with from (3.21). In combination with our complete one-instanton gauge field reads

$$F^0 = \frac{1}{r} \ \frac{z}{y} \ y z \ y s'_1 \ \bar{A} (1) \ @ A (1) \ @ A (1) + [A (1); A (1)] \ \frac{z}{s'_1} \ y \ \frac{1}{s_1} \ \frac{1}{r} \quad (4.25)$$

with abbreviations from (3.28), (3.29), and (4.13). Here, $A (1)$ is obtained by substituting (3.28) into (3.20).

\footnote{It is interesting to note that $S[A^p S_1 + S^p] dS_1$ corresponds to the (singular) $U(2)$ one-instanton configuration produced by the modified ADHM construction \[4p\]. It still fails to be self-dual on $P_0 H$.}
In the commutative limit, our configuration \((A^0;F^0)\) clearly reduces to the BPST instanton because \(S_1 = \text{diag}(1;S_1)\) becomes a unitary matrix and the remaining part of the M vN transformation (mediated by \(U_1\)) turns exactly into the singular gauge transformation from the 't Hooft to the BPST gauge (see [48]). For illustration, the operator \(S_1\) from (4.17) can be rewritten as (cf. [7])

\[
S_1 = y(y + 2)\, y + (1 \ y(y + 2)\, y) z (z + 2) \, z ;
\]

(4.26)

from which one easily sees that in the commutative limit it approaches the identity.

Multi-instanton solutions. Again, a projection (by \(1 \ P_{n+1}\)) plus a M u r r a y-von Neumann transformation (by \(V_n\)) will enable us to extend the projected self-dual solution to the complete Fock space. We decompose \(V_n = S_n U_n\) and propose

\[
S_n = \begin{pmatrix} 1 & 0 \\ 0 & S_n \end{pmatrix} \quad \text{and} \quad U_n = U_1^n U^y ;
\]

(4.27)

where

\[
U = \begin{pmatrix} \Sigma & i \, h_{i+1} h_{i} \\ 0 & 1 \end{pmatrix}
\]

is the unitary transformation from the basis \(f^i\) to the basis \(f^{i+1}\) in \(H\), and \(S_n : H \to (1 \ P_{n+1})H\) is to satisfy the relations

\[
S_n^x S_n = 1 \quad \text{and} \quad S_n S_n^x = 1 \quad \text{for} \quad P_{n+1} = 1 ;
\]

(4.29)

In the orthonormal basis one can choose \(S_n^y\) and \(S_n^x\) in the form

\[
S_n^y = \begin{pmatrix} \Sigma & i \, h_{i+1} h_{i} \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad S_n^x = \begin{pmatrix} \Sigma & i \, h_{i+1} h_{i} \end{pmatrix} ;
\]

(4.30)

Since this basis was constructed from the states \(j_1,i;j_2,i;\cdots;j_n,i\), the operator \(S_n\) contains all the information about the position parameters \(b_1,\cdots,b_n\). It is easy to see that

\[
S_n = U S_1^n U^y
\]

(4.31)

with \(S_1\) from (4.20).

Let us justify our proposal (4.27). Employing the relations

\[
U^{1}_1 = 1 \begin{pmatrix} \Sigma & i \, h_{i+1} h_{i} \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad U^{1}_1 = 1 ;
\]

(4.32)

with

\[
U^{1}_1 = 1 \begin{pmatrix} \Sigma & i \, h_{i+1} h_{i} \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad U^{1}_1 = 1 ;
\]

(4.33)

one can show that

\[
U^{1}_n U_n = 1 \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \quad \text{but} \quad U^{1}_n U^{1}_n = 1 \begin{pmatrix} P_{n+1} & 0 \\ 0 & 1 \end{pmatrix} ;
\]

(4.34)
Together with (4.29) one gets
\[ V_n \gamma V_n = 1 \quad \text{but} \quad V_n V_n^\gamma = \begin{pmatrix} 1 & P_n \ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = (1 \ P_n \ 1) \ \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \] (4.35)

Finally, substituting (3.26) into (3.20), computing its field strength \( F \) and performing the (extended) MVN transformation (4.11) by the matrices (4.27), we learn that the anti-self-dual part of \( F^0 \) indeed vanishes everywhere in \( H \subset C^2 \), again due to \( X_n V_n = 0 = V_n^\gamma X_n \). Hence, our final result
\[ A^0 = V_n^\gamma A^P V_n + V_n^\gamma \theta \ \text{and} \quad F^0 = V_n^\gamma F^P V_n \quad V_n^\gamma F V_n \] (4.36)

constitutes a proper noncommutative generalization of the \( 't \) Hooft n-instanton solution. It has topological charge \( Q = n \) since in the \( \chi = 0 \) limit our solution coincides with the standard \( 't \) Hooft solution, and the topological charge does not depend on . This may also be shown by reducing the action integral to the trace of the projector \( P_n \), following Furuchi [11].

5 Conclusion remarks

Proper noncommutative instantons are constructed by not only replacing the coordinates in the commutative configuration with their operator analogues but also applying a projection and an appropriate M\( \text{VN} \) transformation. We have demonstrated this beyond the (previously considered) case of the one-instanton solution, providing explicit formulae for the field strength (but not the gauge potential) of regular noncommutative \( 't \) Hooft multi-instantons in \( U(2) \). Our results are easily generalized to \( U(N) \). We have pointed out that the M\( \text{VN} \) transformation is needed to remove the source singularities in the reduced SDYM equation, which hamper self-duality on some subspace. In order to take advantage of the M\( \text{VN} \) transformation, however, we had to pass from the original gauge potential to a 'projected' gauge potential in an implicit manner, thereby foregoing an explicit solution for it.

We found it easy to work with the twistor approach because it and the Atiyah-Ward ansätze directly generalize to the noncommutative realm, providing us with a systematic and straightforward strategy for the construction of self-dual gauge-field configurations. In this method, the main task is to find two holomorphic (in and \( \lambda \), respectively) regular matrix-valued operators \( \gamma \) and such that their 'ratio' \( \gamma^{-1} \) defines a holomorphic bundle over noncommutative twistor space with appropriate global properties. In fact, finding solutions to the splitting problem is not made any harder by noncommutativity.

Multi-instantons can also be obtained by employing the dressing approach [50, 51]. In its noncommutative variant, one is to nd a meromorphic (in \( \lambda \)) matrix-valued operator (having nine-order poles in the spectral parameter) which obeys some linear differential equations. The noncommutative dressing method was successfully applied to the study of noncommutative solitons in a \( 2+1 \) dimensional integrable \( \epsilon \) theory [62, 53]. It would be illuminating to also exercise it on the subject of noncommutative instantons and to compare the results with those obtained in the twistor approach.

Finally, noncommutative instantons are interpreted as D\( p \)-branes within coincident D\( (p+4) \)-branes carrying a constant two-form \( B \)-field background [8]. Thus, they have immediate bearing on the issue of nonperturbative string backgrounds.
Aknowledgements

We are grateful to D. Correa and F. Schaposnik for useful comments on an earlier version of this paper. O. L. thanks M. Rocek for fruitful discussions and reading of the manuscript. This work is partially supported by DFG grant Le 838/7-1 and by a sabbatical research grant of the Volkswagen-Stiftung.

A Noncommutative 't Hooft instantons from the ADHM approach

ADHM construction. Here we restrict ourselves to the case of self-dual noncommutative Euclidean space $\mathbb{R}^4$ with the tensor $\Omega$ given by

$$\Omega = \begin{pmatrix} 0 & 1 \\
-1 & 0 \end{pmatrix}$$

where

$$a^i = \begin{cases} 8 & \text{for } i = b; = c \\
4 & \text{for } i = 4 \end{cases}$$

is the self-dual 't Hooft tensor.

Let us introduce the matrices

$$e = i_a ; 1 \quad \text{and} \quad e^y = i_a ; 1$$

which enjoy the properties

$$\begin{align*}
e^y e &= + a_i^a = + \\
e e^y &= + a_i^a = +
\end{align*}$$

Using these matrices one can introduce $x = x^y e$ with $x \in \mathbb{R}^4$.

The (modified) ADHM construction (see [3, 4, 15, 20]) of an $n$-instanton solution is based on a $(2n+2)$ 2 matrix and a $(2n+2)$ 2n matrix $a + b(x_1 \ldots n)$ where $a$ and $b$ are constant. These matrices must satisfy the following conditions:

$$e^y e = + a_i^a = +$$

$$e e^y = + a_i^a = +$$

It is not difficult to see that conditions (A.6) and (A.7) are met if

$$y = 1_2 \quad \text{and} \quad f_n^1 =$$

For $(x_1 \ldots n)$ satisfying (A.6) the gauge potential is chosen in the form

$$A = y \hat{d}$$

15
The resulting gauge field $F$ will be self-dual if and obey the completeness relation

$$ y + (y)^1 \ y = l_{2n+2} : $$

Ansatz. For constructing noncommutative t'Hooft $n$-instantons let us take (cf. [34, 35])

$$ a = \begin{array}{cccc}
0 & 1 & 0 & \cdots \\
1 & 0 & -1 & \cdots \\
\vdots & \vdots & \vdots & \ddots \\
n & 0 & 0 & \cdots 
\end{array} \quad b = \begin{array}{cccc}
0 & 0 & 0 & \cdots \\
1 & 0 & 0 & \cdots \\
\vdots & \vdots & \vdots & \ddots \\
n & 0 & 0 & \cdots 
\end{array} \quad A
$$

with $b_i = b_i e^y$. It follows that

$$ y = l_2 \ (i r_j^2 + i_j) = : l_2 \ (R + R^T) ; $$

where

$$ R = \begin{array}{c}
0 \ r_1^2 \\
\vdots \\
\ddots \\
1 \\
r_n^2 
\end{array} \quad (1; \cdots ; n) ; \quad r_j^2 = (x \ b_j)(x \ b_j) ; $$

and the $i$ are constants parametrizing the scale of the $i$th instanton. From (A.14) we see that the condition (A.10) (and thus also (A.9) and (A.7)) is satisfied. Indeed, by direct calculation one nds

$$ l_2 f_n = (y)^1 = l_2 \ R^l R^1 \ R_{1}^l \ n \ R^1 $$

with

$$ n = 1 + \frac{x^2}{\sum_{i=1}^{2} r_i^2} ; $$

For the given $b = a + b(x \ l_n)$ and $x_i = (x \ b_i) e^y$, the condition (A.2) becomes

$$ i_0 + x_i^y = 0_2 \quad \text{for} \quad i = 1; \cdots ; n ; $$

These equations are solved by

$$ 0 = n \ \frac{1}{l_2} \ l_2 \quad \text{and} \quad i = x_i \ \frac{1}{l_1} n \ \frac{1}{l_2} $$

where the factor $n \ \frac{1}{l_2}$ was introduced to achieve the normalization

$$ y = n \ \frac{1}{l_2} 1 + \frac{x^2}{\sum_{i=1}^{2} r_i^2} \ l_2 \ n \ \frac{1}{l_2} = l_2 ; $$

Hence, our $(; ;)$ satisfies all conditions (A.6) (A.10) and we can present the gauge potential (A.13).
Complete\textup{ness} relation. Being convinced that they have constructed self-dual \textup{eld} configurations, many authors stop at this point and ignore the complete\textup{ness} relation \eqref{A.12}. However, the latter may be violated, in which case one obtains a singular \textup{eld} configuration (cf.\ the discussion in \cite{20}). Indeed, our example solution \eqref{A.13} indicates just that. Namely, after (lengthy) \textup{com}putations we arrive at

\[ y + ( y )^\dagger y = l_{2n+2}; \quad \text{(A.21)} \]

where \textit{is} a projector,

\[
\begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
1 & x_1 & x_1 & 0 \\
\vdots & \ddots & \ddots & \ddots \\
0 & 1 & 0 & 0 \\
1 & x_n & x_n & 0
\end{pmatrix}
\]

and \[ l_{2n+2} x_1 x_1 y = \beta_i \beta_j 0 
\]

\text{(A.22)}

Here, the \( \beta_i \) \textit{are the coherent states defined in} \eqref{3.32}. Notice that in the commutative limit \( \lambda \to 0 \), and the completeness relation will be saturated.

\textbf{Field strength.} \textit{We} finally evaluate the \textup{eld} strength. Substituting \eqref{A.19} into \eqref{A.11} and using \eqref{A.21}, we find

\[
F = \mathfrak{e}^y ( y )^\dagger y e^y + n^\frac{1}{2} e^y \sum_{i=1}^{\frac{n}{2}} \beta_i \beta_j n^\frac{1}{2} 2
\]

\[
= 2 \beta \mathfrak{e}^y ( y )^\dagger y e^y + n x_2 \sum_{i=1}^{\frac{n}{2}} \beta_i \beta_j n^\frac{1}{2} 2
\]

\text{(A.23)}

where \( X_n \) is precisely the source term \eqref{3.31} derived earlier in the twistor approach. We conclude that the anti-self-dual part of \( F \) is nonzero and, in complex coordinates, coincides with the r.h.s. of \eqref{3.23}. Hence, the ADHM approach encounters exactly the same obstacle as the twistor method.
