Abstract

We propose a modified mode-expansion of the bulk fields in a BPS domain wall background to obtain the effective theory on the wall. The broken SUSY is non-linearly realized on each mode defined by our mode-expansion. Our work clarifies a relation between two different approaches to derive the effective theory on a BPS wall, i.e., the non-linear realization approach and the mode-expansion approach. We also discuss a further modification that respects the Lorentz and U(1)$_R$ symmetries broken by the wall.
1 Introduction

In supersymmetric (SUSY) theories, there are important states called BPS states. They preserve part of the supersymmetry of the theory and play a crucial role in quantum field theories. One of the simplest examples of BPS states is a BPS domain wall. In particular, BPS domain walls in four-dimensional (4D) $N = 1$ SUSY theories have been thoroughly investigated in a number of papers because such theories are tractable and have various types of BPS walls with interesting features.

Besides that BPS domain walls are an intriguing subject to research in their own right, they are also important in the braneworld scenario because they can provide a natural realization of 5D $N = 1$ SUSY (eight supercharges) to 4D $N = 1$ SUSY (four supercharges), which is relevant to the phenomenology. Of course, since our world is four-dimensional, we should discuss a domain wall in 5D theories for the realistic model-building. However, 5D SUSY theory is quite restrictive and difficult to handle. So it is useful and instructive to study BPS walls in 4D $N = 1$ theories as a toy model. In this paper, we will concentrate ourselves on BPS walls in the 4D $N = 1$ generalized Wess-Zumino model for simplicity. To discuss the physics in the BPS-wall background, it is useful to investigate a low-energy effective theory on the wall. Since a BPS wall preserves a half of the bulk SUSY, such an effective theory can be expressed by 3D superfields. There are mainly two approaches to derive the effective theory described by 3D superfields.

The first one is the non-linear realization approach. From the 3D viewpoint, SUSY breaking by a BPS wall can be regarded as the partial SUSY breaking from 3D $N = 2$ to $N = 1$. Thus, we can obtain the effective theory on the wall by constructing an invariant action under the broken SUSY, which is realized non-linearly. This approach is useful for the discussion of the general properties of BPS supermembranes since this method uses only information on the breaking pattern of the symmetries. This also means, however, that we cannot determine parameters of the effective theory in this approach.

The second one is the mode-expansion approach. In this approach, the 3D effective theory is directly derived from the original 4D theory. Specifically, we expand the fluctuation fields around the wall-background into an infinite number of 3D superfields, and integrating out the heavy modes. In this approach, we can see explicitly how the 3D superfields in the effective theory are embedded into the original 4D superfields. Unlike the previous approach, parameters of the effective theory are obtained as the overlap integrals of the background fields configuration and the mode functions. However, this approach does not respect the symmetries broken by the wall.

These two approaches are complementary to each other. So it is useful and instructive to clarify the relation between them. This is the purpose of this paper. Specifically, we will propose the modification of the naive mode-expansion of the bulk superfields so that the broken SUSY is non-linearly realized on each mode. Using our modified mode-expansion, we can obtain an invariant effective action under the broken SUSY, and can also calculate parameters of the effective theory. In the latter part of this paper, we try to modify the mode-expansion further so that it also respects the Lorentz and $U(1)_{R}$ symmetries.
by the wall.

The paper is organized as follows. In the next section, we will provide a brief review of the nonlinear realization approach. In Sec2, we will review our previous work [12] where a naive mode-expansion is discussed. Then, in Sec3, we will modify it so that the broken SUSY is nonlinearly realized on each mode. In Sec4, we will discuss the further modification of the mode-expansion which also respects the broken Lorentz and $U(1)_R$ symmetries. Sec5 is devoted to the summary and the discussion. Notations and some formulae are listed in the appendices.

2 Review of the nonlinear realization approach

In this section, we will briefly review the nonlinear realization approach to construct an effective action for the supermembrane [10]. Throughout this paper, we will assume that the background space-time is flat and has a 4D $N = 1$ supersymmetry.

From the 3D viewpoint, the 4D $N = 1$ SUSY algebra is a central extended $N = 2$ SUSY algebra.

\[
\begin{align*}
  f Q_1 ; & Q_1 g = f Q_2 ; Q_2 g = 2 (m^{(3)}_2) P_m ; \\
  f Q_1 ; & Q_2 g = f Q_2 ; Q_1 g = 2 i (m^{(2)}_2) P_2 ;
\end{align*}
\]

where $m = 0; 1; 3$ denotes the 3D space-time index, and $;$ denote the 3D Majorana spinor indices\(^1\).

The existence of the BPS membrane breaks the bulk symmetry $G = f P_m ; P_2 ; Q_1 ; Q_2 g$ to the vacuum stability subgroup $H = f P_m ; Q_2 g$. Then, a coset element can be parametrized as

\[
  e^{i x^m P_m + i x^2 e^{i \theta} P_2 + i Q_1} ;
\]

Here $0 = 0(x^m ; 2)$ and $0 = 0(x^2 ; 2)$ are scalar and spinor superfields corresponding to the Nambu-Goldstone (NG) modes for $P_2$ and $Q_1$, respectively, and $\theta$ is a constant whose mass dimension is $3=2$.

The transformation laws of each superfield for the broken symmetries can be read off as follows by multiplying corresponding group elements from the left.

\[
\begin{align*}
  P_2 & a 0 = a ; \\
  P_2 & a 0 = P_2 a 0 = 0 ;
\end{align*}
\]

\[
\begin{align*}
  Q_1 & 1 0 = 2^1 1 2^1 1 m^{(3)}_2 0 @m 0 ; \\
  Q_1 & 1 0 = 1^1 1 1^1 1 m^{(3)}_2 0 @m 0 ; \\
  Q_1 & 1 1 = i^1 1 m^{(3)}_2 0 @m ;
\end{align*}
\]

\(^1\) In this paper, we will choose the $x_2$-direction to be perpendicular to the membrane or the domain wall.

\(^2\) The mass scale $f^{2m^2}$ corresponds to the scale where $P_2$ and $Q_1$ are broken, and $f^{3} = 2^3$ is a tension of the membrane.
where \( a \) and \( b \) are transformation parameters, and \( P \) denotes a matter super field. Indeed, the above transformations satisfy the SUSY algebra \( [\mathbf{1}] \). In this paper, we will call the above transformation laws for the broken symmetries the standard non-linear transformations.

Note that the NG super fields \( P \) and \( Q \) introduced by Eq. (2) are not independent of each other, because the NG modes for \( P_2 \) and \( Q_1 \) form a super multiplet for the unbroken \( Q_2 \)-SUSY. The relation between them can be obtained by setting a covariant constraint (inverse Higgs sector [13]),

\[
D_2^2 P = 0; \tag{5}
\]

where \( D_2 \) is a covariant spinor derivative in the presence of the NG super fields, and its explicit form is listed in Eq. (84) in Appendix A. From this constraint, we can express \( P \) in terms of \( Q \).

\[
0 = \frac{1}{2} D_2^2 P + O(2): \tag{6}
\]

Namely, the essential NG super field is \( P(x^m; \lambda) \) only.

By using \( D_2 \), we can construct a 3D \( N = 2 \) invariant action perturbatively for the standard procedure of the non-linear realization [11].

For an invariant action for the NG modes \( S_{NG} \), there is an alternative method to derive the effective action for all orders in \( \lambda \) [10, 14]. We will explain this method in the following.

Let us introduce a scalar NG super field \( P^0(x^m; \lambda) \). As will be shown, \( P^0 \) coincides with \( P \) at the lowest order in \( \lambda \). Then, denote a spinor super field \( P^0(x^m; \lambda) \) as

\[
0 = \frac{1}{2} D_2^2 P^0; \tag{7}
\]

This means that \( P^0 \) satisfies the following constraint.

\[
D_2^2 P^0 = 2i (\frac{\partial}{\partial \lambda} P): \tag{8}
\]

Noticing that \( P^0 \) is the NG super field for \( Q_1 \), we can write its \( Q_1 \)-transformation law which preserves the constraint [3] and satisfies the SUSY algebra \( [\mathbf{2}] \) as

\[
Q_1 P^0 \equiv 1_{10} = 1_{10} + \frac{1}{4} D_2^2 \frac{i}{2} (\frac{\partial}{\partial \lambda} P): \tag{9}
\]

Here, \( P \) is a scalar super field and transforms under the \( Q_1 \) transformation as

\[
Q_1 P = 2 \frac{1}{2} P \equiv 1_{10} = 1_{10} D_2 P^0: \tag{10}
\]

From Eqs. (2) and (11), we can see that sat the following recursive equation.

\[
= \frac{\frac{2}{4}}{1 + \frac{1}{4} D_2^2}: \tag{11}
\]
This equation can be solved and the solution is

\[ \frac{q 2^\frac{3}{6}}{1 + 1 + 2D_2^2(\frac{3}{6})} : \]  

(12)

From the transformation law (10), we can see that

\[ S_{NG} = d^3x d^2 \frac{1}{2}(D_2' \cdot 0)^2 + O(\cdot^2) : \]  

(13)

is $Q_1$-invariant. So this is a good candidate for the effective action of the NG modes. The right-hand-side of Eq. (13) is expanded by as

\[ S_{NG} = d^3x d^2 \frac{1}{2}(D_2' \cdot 0)^2 + O(\cdot^2) : \]  

(14)

This certainly is an action for a massless super field. Actually, after eliminating the auxiliary field of $0$, the bosonic part of $S_{NG}$ becomes the Nambu-Goto action in the static gauge. (See Appendix [E].)

Now we define the quantity

\[ E = \frac{1}{1 + \frac{2}{2}D_2} : \]  

(15)

Then the relation between $0$ and $0$ can be written by

\[ 0 = \frac{0}{E} : \]  

(16)

In fact, we can easily show that the right-hand-side of this equation transforms as $0$ in Eq. (4) under the $Q_1$-SUSY.

From Eq. (16), we can see that

\[ 0 = 0 + O(\cdot^2) : \]  

(17)

This means that

\[ 0 = 0 + O(\cdot^2) ; \]  

(18)

as mentioned before.

Using $E$ defined by Eq. (15), an invariant action for a matter field can be written in the form of

\[ S_{\text{matter}} = d^3x d^2 \frac{1}{2} E F(\cdot ; D_2 ; D_m ; \cdot) ; \]  

(19)

where $F$ is a 3D Lorentz invariant function of and its covariant derivatives.

From Eqs. (9) and (7), we can read off the $Q_1$-transformation law of $0'$ as

\[ Q_{1/1}' 0 = 2 \frac{1}{1 + 2} + 1D_2 : \]  

(20)

If we define a complex scalar super field

\[ 0 = 0' + i\cdot^2 ; \]  

(21)
Eqs. (10) and (20) are collectively written as\(^3\)
\[
Q^1_1 \cdot 0 = 2_1 2_1 i_1 D_2 0: \quad (22)
\]

The \(P_2\)-transformation law of \(0\) can be defined as
\[
P^2_0 = a: \quad (23)
\]

Eqs. (22) and (23) form the SUSY algebra [11].

3 Mode-expansion approach

Now we will discuss the mode-expansion approach to obtain the effective action on the BPS wall. Here we will consider the 4D \(N = 1\) generalized Wess-Zumino model as a bulk theory. The action is
\[
S = \int d^4x d^2 \theta \ K ( \cdot ) + \int d^4x d^2 \omega ( \cdot ) + \int d^4x d^2 W ( \cdot ) ; \quad (24)
\]
where \(i\) are (anti-) chiral super fields and
\[
i(y; \cdot ) = A^i(y) + \bar{Z} i_1(y) + \bar{F} i_1(y); \quad (y = x + i) \quad (25)
\]

We assume that this theory has a BPS domain wall \(A^i = A^i_{cl}(x_2)\). The classical solution \(A^i_{cl}(x_2)\) satisfies the following BPS equation.
\[
\theta_2 A^i = e^i K i j W_j ; \quad (26)
\]

where \(\theta_2 = \theta_2 x_2\), and \(K i j\) is an inverse matrix of the Kähler metric \(K_{i j}\). Lower indices denote derivatives in terms of corresponding super fields. is a phase determined by \(A^i_{cl}\),
\[
\arg dW ; \quad (27)
\]
where \(\theta_2\) is an orbit for \(A^i_{cl}(x_2)\) on the target space of the scalar field.

Now we decompose the Grassmannian coordinates and as
\[
= \frac{e^i = 2}{2} (1 + i_2); \quad - = \frac{e^i = 2}{2} (1 + i_2); \quad (28)
\]

where \(i\) are 3D Majorana spinors, and corresponding to this, we decompose the supercharges as
\[
Q = \frac{e^i = 2}{2} (Q_1 + i Q_2); \quad Q = \frac{e^i = 2}{2} (Q_1 + i Q_2); \quad (29)
\]

\(\text{By using } \theta_2, \text{we can construct a linear realization for partial SU SY breaking: 3D } N = 2 ! N = 1 [15].\)
Then it follows that
\[ Q \circ + \circ Q = \circ _1Q_1 + \circ _2Q_2: \]
(30)

In this case, \( Q_1 \) and \( Q_2 \) correspond to the broken and the unbroken supercharges, respectively. Under the decomposition \( [28] \), the 4D \( N = 1 \) SUSY algebra is rewritten as Eq. [1].

After performing the integration in terms of \( \circ _1 \), the original action \( [24] \) becomes \( [12] \)
\[
S = Z \int d^4x \int d^2x_2 \; K_{ij}D_{2} \circ _1D_{2} \circ _2 \circ _1 \circ _1 + 4 \Im \; e^{\circ _1 W (')}: \quad (31)
\]

Here
\[ \circ _1(x^m ; x_2; 2) = e^{i\circ _1P_1 + i\circ _1P_2} A_1(0); \quad (32) \]

where the definition of the action of the generators on the fields is given in Appendix A. 2, and its relation to the 4D chiral superfield \( \circ _1 \) is
\[ \circ _1(x^m ; x_2; 1; 1; 2) = e^{iD_2 \circ _1 \circ _1 \circ _1} \circ _1(x^m ; x_2; 2): \quad (33) \]

Using \( \circ _1 \), we can rewrite the superfield equations of motion
\[ \frac{1}{4} D^2K_1 + W_1 = 0; \quad (34) \]
as
\[ \frac{1}{2} K_{ij}D_2 \circ _1D_2 \circ _1 + \circ _1D_1 \circ _1 \circ _1 + e^{iW_1} = 0; \quad (35) \]

Then, the equations of motion for the action \( \circ _1 \) around the background \( \circ _1 = A_1(x_2) \) can be obtained by substituting \( \circ _1 = \circ _1 + \circ _1 \) into Eq. [35]. Using the BPS equation \( [24] \), it can be written as
\[ \frac{1}{2} K_{ij}(A_1)D_2 \circ _1D_2 \circ _1 + \circ _1D_1 \circ _1 \circ _1 + e^{iD_1(A_1)} \circ _1 + \circ _1 \circ _1 = 0; \quad (36) \]

where the ellipsis denotes higher terms for \( \circ _1 \), and
\[ \circ _1 = K_{ij}(A_1) \circ _1; \quad D_1 \circ _1 = D_1 \circ _1 + \circ _1 \circ _1 \circ _1; \quad D_1W_j \circ _1 = D_1W_j \circ _1 \circ _1 \circ _1 \circ _1 \circ _1 \circ _1 \circ _1 \circ _1 \;
\]

Here \( K_{ij} \) is a connection on the Kähler manifold. From Eq. [36], we can find the mode equation,
\[ \circ _1D_1u_{(n)} + e^{iD_1(A_1)}u_{(n)} = m_{(n)}u_{(n)}; \quad (38) \]

where \( u_{(n)} = K_{ij}(A_1)u_{(n)} \).

Using the mode function \( u_{(n)}(x_2) \), we can expand the 4D \( \circ _1 \) as
\[ \circ _1(x^m ; x_2; 2) = A_{(n)}(x_2) + \frac{1}{2} \sum_{n=0}^{\infty} u_{(n)}(x_2) \circ _1(x^m ; 2): \quad (39) \]
Here we have chosen the normalization of $u_{(n)}^i(x_2)$ as
\[
\int x_2 \Re u_{(n)}^i(x_2) u_{(m)}^i(x_2) = \delta_{nm} \quad (40)
\]

By substituting Eq. (39) into Eq. (31) and performing the $x_2$-integration, the original 4D action can be rewritten in terms of infinite 3D superfields as follows.
\[
S = \int d^3x d^2\tau \sum_{n=0}^\infty \left[ \frac{1}{2} \left( D_2'_{(n)} \right)^2 + m_{(n)}^2 \right] + \text{(interaction terms)} \quad (41)
\]

Finally, by integrating out the heavy modes, we can derive the low-energy effective action on the domain wall.

4 Mode-expanded mode-expansion

4.1 Nambu-Goldstone mode

In the expression, the $Q_2$-SUSY is manifest since it is written in terms of superfields for the $Q_2$-SUSY. However, the nonlinear $Q_1$-SUSY is not clear. In fact, the $Q_1$-transformation of each mode $'_{(n)}$ defined by the mode-expansion (39) does not close on $'_{(n)}$.

Considering Eq. (39) and the $Q_1$-transformation of the 4D field $'_{i}$, which is derived in Appendix C, we can extract the $Q_1$-transformation law of $'_{(n)}$ as follows.
\[
Q_1'_{(n)} = 2^{1/2} \sum_{n\neq 0} \left[ X_{nm} U_{nm}'_{(m)} + V_{nm} D_2'_{(m)} \right] \quad (42)
\]

where
\[
\int dx_2 K_{ij}(A_{cl}) \partial_2 A_{cl}^i \partial_2 A_{cl}^j + K_{ij}(A_{cl}) W_1(A_{cl}) W_2(A_{cl}) \quad (43)
\]
is the tension of the domain wall, and
\[
U_{nm} = \int dx_2 \Re u_{(n)}^i(\partial_2 u_{(m)}^i) \quad (44)
\]
\[
V_{nm} = \int dx_2 \Im u_{(n)}^i(\partial_2 u_{(m)}^i) \quad (44)
\]

Here we have used the fact that
\[
\frac{1}{2} u_{(0)}^i(x_2) = \partial_2 A_{cl}^i(x_2) \quad (45)
\]

\[\text{We have assumed eigenvalues } m_{(n)} \text{ to be real. See Appendix C in Ref. [14].} \]
We can derive the $P_2$-transformation law of $'_{(n)}$ in a similar way.

\[ P_2 \cdot '_{(n)} = a \sum_{m} X_{nm} U_{nm} '_{(n)} \]  

(46)

As mentioned above, either transformation (42) or (46) does not close on each $'_{(n)}$.

Next, we will modify the mode-expansion (39) so that the broken symmetries $Q_1$ and $P_2$ are non-linearly realized on each mode. Consider the following mode-expansion.

\[ '_{(n)}(x_2; x_2) = A_{1}^i (x_2 + 0) + \frac{1}{2} \sum_{n \neq 0} X_{nm} U_{nm} '_{(n)}(x_2; x_2); \]  

(47)

where $0$ is a complex scalar function of the NG mode $'_{0}$. From this mode-expansion and Eqs.(98) and (99) in Appendix C, the transformation laws of $'_{0}$ are read off as

\[ Q_1 \cdot '_{0} = 2_{1} 2_{1} 2_{2} 0_{2}; \]

\[ P_2 \cdot '_{0} = a; \]  

(48)

These coincide with Eqs.(22) and (23). Therefore, $'_{0}$ defined by the modified mode-expansion (47) can be identified with $'_{0}$ in Eq.(13) in the previous section.

Indeed, by substituting Eq.(47) into Eq.(31), dropping the massless modes $'_{(n)} (n \neq 0)$, and carrying out the $x_2$-integration, we will reproduce the supersymmetric Nambu-Goto action Eq.(13).

4.2 Matter action

Although the NG mode $'_{0}$ is identified with that of the non-linear realization in the mode-expansion (47), the $Q_1$-transformation law of the other modes $'_{(n)} (n \neq 0)$ does not close on their selves. Then, in this subsection, we will further modify the mode-expansion so that $'_{(n)} (n \neq 0)$ transforms in the standard non-linear transformation under the $Q_1$-SUSY.

Before we proceed, let us comment on the validity of such modification. From the 3D viewpoint, the modification of mode-expansion from Eq.(39) to Eq.(47) corresponds to the redefinition of the super field $'_{(n)}$. Note that such redefinition involves space-time derivatives. In fact, although the original theory (24) contains no derivative couplings, the resulting effective theory has derivative couplings. (See Eq.(13) or (24).) Hence, this redefinition induces a new cut-off scale into the theory, which is $f^{2-3}$.

Naively thinking, the mass of the first excited mode is thought to be $0$ ($f$), and thus all modes except the NG mode $'_{0}$ in Eq.(47) should be integrated out. However, there can be exist modes lighter than the cut-off scale $f$ in some models. For example, the theory with

\[ K ( ; ; X ; X ) = X^{3}; \]

\[ W ( ; X ) = \frac{g}{3} h X^{3}; ( ; g; h > 0) \]  

(49)

8
has the following BPS domain wall.

\[ A_{\text{cl}}(x_2) = \frac{1}{P \bar{g}} \tanh(P \bar{g} x_2); \]

\[ A_{\text{cl}}^X(x_2) = 0; \]

(50)

In this case, the dynamical scale of the domain wall \( f \) is

\[ f = \frac{8}{3P \bar{g}} \]

(51)

and a matter \( \text{ex} \) contains modes with the mass eigenvalues \[16, 17]\]

\[ m_{(n)} = \sqrt{n \frac{4h}{g} + n P \bar{g} : n = 0, 1, 2; \quad 2h \frac{P}{g} < 1} \]

(52)

This means that in the case of \( g \quad h < 1 \), which corresponds to the fat brane \[13\], there are many light modes which satisfy the condition \( m_{(n)} \quad f \). In the braneworld model-building, such light modes, especially the massless modes besides the NG mode, play important roles. Therefore, the further modification of the mode-expansion involving the \( \text{matter} \) modes \( \epsilon_{(n)} \quad (n \neq 0) \) is a useful work.

The modified mode-expansion is

\[ \epsilon_{(n)} = A_{\text{cl}}^X(x_2 + 0) + \frac{1}{2} \sum_{n \neq 0}^{X} \epsilon_{(n)}(x_2 + 0); \]

(53)

with

\[ \epsilon_{(n)} = i D_{(n)}^{0} D_{(n)}^{2} + \frac{1}{2} D_{(n)}^{2} U_{(n)}^{0}; \]

(54)

Here, \( P_{(n)}^{a} \) is defined by Eq. \[14\]. In this case, each mode transforms under the broken symmetries as follows.

\[ P_{(n)}^{a} = 0; \]

\[ Q_{(n)}^{a} = \frac{1}{2} \theta_{m}^{(0)} + O(2); \]

(55)

These coincide with Eqs. \[3\] and \[4\] up to \( O(1) \).

In fact, by substituting Eq. \[53\] into Eq. \[31\], we can obtain the following Lagrangian with some what tedious calculation\[5\].

\[ L^{(3)} = \sum_{n \neq 0}^{X} D_{(n)}^{2} U_{(n)}^{0} + \sum_{n \neq 0}^{X} \frac{1}{2} D_{(n)}^{2} + m_{(n)}^{2} + \nabla^{2} \epsilon_{(n)} + \nabla^{2} \epsilon_{(n)}^{0} \]

(56)

\[ + \frac{1}{2} D_{(n)}^{2} D_{(n)}^{2} + D_{(n)}^{2} D_{(n)}^{2} + \nabla^{2} \epsilon_{(n)} + \nabla^{2} \epsilon_{(n)}^{0} \]

\[ + O(3) \]

\[ ^{5}\text{For simplcity, we have assumed the minimal Kähler potential.} \]
where $E$ is defined by Eq. (15), and
\[
Z \sum_{n=0}^{N} d x_2 \Re u_{(n)}^i u_{(n)}^i \; + \;
V \sum_{n=0}^{N} d x_2 \Im e^{i \frac{1}{N!} u_{(n)}^i u_{(n)}^i \; + \; \frac{1}{(n_1) \ldots (n_N)} \; + \; m_{(n)} \; + \; V (\; (n) \; )}.
\]

The above Lagrangian certainly has an invariance under the $Q_1$-SUSY, which is nonlinearly realized. The first term is the supersymmetric Nambo-Goto Lagrangian, and the remaining part corresponds to the matter Lagrangian.

5 Broken Lorentz and $U(1)_R$ symmetries

In the matter Lagrangian in Eq. (56), note that the NG mode $\gamma_0$ appears not only through $E$ and $D_2$, but also in the form such as $D_2 \phi$. This means that even if we know the Lagrangian in the limit of $\gamma_0$ in some way, we cannot reproduce the full Lagrangian Eq. (56) by using the method of the nonlinear realization. This stems from the fact that we did not respect the broken Lorentz symmetry and the $U(1)_R$ symmetry in the modification of the mode-expansion (53) and (54).

In the nonlinear realization for space-time symmetries, if we take into account only the (super-)translational generators as generators of the whole bulk symmetry $G$, there will be an ambiguity of inserting a dimensionless tensor, such as $D_{2 \phi}$, into the $G$-invariant effective action (11). For example, let us assume that the Lagrangian at $\gamma_0$ is
\[
L^{(3)} = \sum_{n=0}^{N} d x_2 \Re e^{i \frac{1}{N!} u_{(n)}^i u_{(n)}^i \; + \; m_{(n)} \; + \; V (\; (n) \; )}.
\]

Then, the most general Lagrangian that is $P_2$- and $Q_1$-invariant is written as
\[
L^{(3)} = \sum_{n=0}^{N} d x_2 \Im e^{i \frac{1}{N!} u_{(n)}^i u_{(n)}^i \; + \; m_{(n)} \; + \; V (\; (n) \; )} + F (D_2 \phi ; D_2 \phi ; D_2 D_2 \phi ; \ldots)
\]

where $F$ denotes 3D Lorentz-invariant terms that include at least one covariant derivative of $\gamma_0$. Note that the above Lagrangian has an ambiguity of adding terms including arbitrary numbers of $D_{2 \phi}$ since such a tensor is dimensionless. In fact, the second and

\[\text{In fact, such Lagrangian can be calculated much easier than Eq. (56) since Eqs. (53) and (54) become very simple form s by dropping } \gamma_0 \text{ (and thus } \phi) \text{ from Eq. (53).}\]
the third lines in Eq. (56) correspond to $F$ in Eq. (55), and cannot be determined by the nonlinear realization.

The above ambiguity already exists in the definition of $\kappa_n$ in Eq. (54). We may add terms, such as $\mathcal{D}_2 0 \kappa_n$, to the definition of $\kappa_n$ since the resulting transformation laws of $\kappa_n$ do not change. Such terms contribute to $F$ in Eq. (59).

In order to remove such ambiguity, we should take the full symmetry group $G$ as

$$G_{\text{max}} = \mathcal{F} \mathcal{P} \mathcal{Q}_1 ; \mathcal{Q}_2 ; \mathcal{P} \mathcal{M}_{mn} ; \mathcal{K}_m ; \mathcal{R} ; \mathcal{G} ; \mathcal{E}$$

which contains the maximal automorphism group of the 4D $N = 1$ SUSY algebra. Here $\mathcal{M}_{mn}$ and $\mathcal{K}_m$ denote the 4D Lorentz generators, and $\mathcal{R}$ is a generator of $U(1)$. In this case, the vacuum stability subgroup is

$$H_{\text{max}} = \mathcal{F} \mathcal{P} \mathcal{M}_{mn} \mathcal{G} ; \mathcal{E}$$

The algebra among these generators is listed in Eq. (102) in Appendix D.1.

The transformation laws of $\kappa_n$ in the nonlinear realization under the $K$- and $R$-transformations can be defined by

$$K_{\nu} 0 = \nu^n x_{\nu} 0 \partial_{\nu} 0 + \frac{1}{2} (3\nu) D_2 0 \partial_{\nu} 0 ; \quad (62)$$

$$R_\rho 0 = r^\rho + \frac{1}{2} i_2 D_2 0 \partial_{\nu} 0 ; \quad (63)$$

where $\nu^n$ and $r$ are transformation parameters. These form the SUSY algebra (102) together with Eqs. (22) and (23).

From Eq. (62),

$$K_{\nu} = \nu^n x_{\nu} (0) + \frac{1}{2} i_2 (3\nu) D_2 0 (0) \partial_{\nu} 0 : \quad (64)$$

This is a total derivative and thus the NG action $S_{\text{NG}}$ in Eq. (13) is invariant under the $K$-transformation.

For the $U(1)_R$ symmetry, on the other hand, we can see from Eq. (63),

$$R_\rho = r^\rho D_2 0 \partial_{\nu} 0 ; \quad (65)$$

This means

$$R_{\rho} S_{\text{NG}} = r^{\rho} \partial_{\nu} 0 d^3x 2f_0 ; \quad (66)$$

where $f_0$ is the auxiliary field of $0$. So $S_{\text{NG}}$ does not have the o-shell $U(1)_R$ symmetry. However, considering the fact that $f_0 = 0$ on shell as mentioned in Appendix B, we can see that $S_{\text{NG}}$ is $R$-invariant on shell.

As a result, $S_{\text{NG}}$ obtained in the nonlinear realization is invariant under the full $G_{\text{max}}$ symmetry.

On the other hand, the NG action obtained by the mode-expansion (53) does not have an invariance under the broken Lorentz symmetry. Although it has the same form as
Eq. (13), the $K$-transformation of $\theta_0$ does not coincide with Eq. (62). Unlike the non-linear realization, the transformation laws of each mode are determined from those of the bulk theory in the mode-expansion approach. The $K$-transformation law of $\theta_1$ is listed in Eq. (106) in Appendix C. Due to the explicit appearance of $x_2$ in Eq. (100), the $K$-transformation of $\theta_0$ does not close on $\theta_0$.  

Now we will try to modify the mode-expansion (53) further, so that $\theta_0$ transforms properly under all broken symmetries $G_{\text{max}} = H_{\text{max}}$.

We propose the following mode-expansion.

$$\xi(x^m; x_2; 2) = A_{\alpha_2}(x_2) + \frac{1}{2} \sum_{\alpha \neq 0} X^i_{\alpha}(x_2) \xi_{\alpha}^{(m)}(x^m; 2); \tag{67}$$

where

$$x^m = x^n, \quad x_1 @^m = \frac{2}{2} @^m (\xi_0^2) + \frac{2}{2} x_2 @^m (\xi_0^2, \xi_0^2) + O(3); \tag{68}$$

and $\xi_{\alpha}$ is the one defined in Eq. (54).

With this mode-expansion and Eq. (100), we can derive the $K$-transformation of each mode.

$$K_{\alpha}^{\alpha} = \psi^m_\alpha + \frac{1}{2} \psi^m_\alpha (\psi^m_\alpha) D_{\alpha 0} + O(2); \tag{69}$$

$$K_{\alpha}^{\alpha} = \psi^m_\alpha + \frac{1}{2} \psi^m_\alpha (\psi^m_\alpha) D_{\alpha 0} + O(2); \tag{70}$$

Eq. (69) coincides with Eq. (62) up to $O(\psi)$. Considering the definition of $\xi_{\alpha}$ in Eq. (54), Eq. (70) is translated into

$$K_{\alpha}^{\alpha} = \psi^m_\alpha + \frac{1}{2} \psi^m_\alpha (\psi^m_\alpha) D_{\alpha 0} + O(2); \tag{71}$$

Noticing that $\psi_0 = \psi_0 + O(2)$, this coincides with the standard non-linear transformation Eq. (103) in Appendix D.

In a similar way, we can derive the transformation laws for other symmetries. For the broken SUSY, we obtain

$$\frac{Q^1_1}{1} = \frac{2}{1} Y_{12} i_{12} D_{20} + O(2); \tag{72}$$

$$\frac{Q^1_1}{1} = \frac{2}{1} Y_{12} i_{12} D_{20} + O(2); \tag{73}$$

For the $U(1)$ symmetry, by using Eq. (104) in Appendix C, we obtain

$$\frac{R^r_0}{r_0} = r(\frac{1}{2} + i_{02} D_{20}) + O(2); \tag{74}$$

$$\frac{R^r_0}{r_0} = r(\frac{1}{2} + i_{02} D_{20}) + O(2); \tag{75}$$
Thus, it transforms in the desired way in the case of our modified mode-expansion (67) and (68). Note that Eqs. (73) and (75) are the standard nonlinear transformations, which are listed in Eq. (103) and (107) in Appendix D. Therefore, the modified mode-expansion (67) and (68) defines modes on which all the broken symmetries are nonlinearly realized at least up to $O(\lambda^2)$.

6 Summary and discussion

There are mainly two different approaches to derive the low-energy effective theory in the background of a BPS domain wall. Each approach has its own advantages and disadvantages.

The first one is the nonlinear realization approach. We can construct an effective action on the wall that is invariant under both the broken and the unbroken SUSYs by using the nonlinear realization technique. This approach is useful when we discuss the general properties of BPS brane-like objects, such as BPS walls or supermembranes. However, in this approach, we neglect the wall width and cannot discuss the specific wall profile. Namely, we cannot determine parameters of the effective theory by this approach.

The second one is the mode-expansion approach. In this approach, we start directly from the bulk theory. So we need to specify the bulk theory and thus the results are model-dependent. Since we explicitly derive the effective theory from the bulk theory, the relation between the bulk 4D superfields and the 3D superfields in the effective theory is clear in this approach. On the other hand, SUSY broken by the wall is not respected since its transformation of each mode does not close on itself.

Therefore, it is very useful and instructive to clarify the relation between the above two approaches.

In this paper, we proposed a modified mode-expansion so that the broken SUSY is nonlinearly realized on each mode. Indeed, our mode-expansion leads to a supersymmetric Nambo-Goto action for the NG mode, and to a matter action with a form expected from the nonlinear realization for the other modes. In particular, the NG mode's definition by our mode-expansion can be identified with that of the nonlinear realization for all orders in $\lambda$. For the other modes, their transformation law under the broken SUSY coincides with the standard nonlinear transformation up to $O(\lambda^2)$.

Note that our modification of the mode-expansion corresponds to the redefinition of the 3D superfields. This redefinition involves space-time derivatives and the scale $f^{2/3}$. So the cut-off scale of the effective theory becomes $f$ after the redefinition.

We also showed that it is possible to modify the mode-expansion so that each mode transforms in the standard nonlinear transformation under not only the broken SUSY but also the broken Lorentz and $U(1)_{h}$ symmetries at least up to $O(\lambda^2)$. However, whether the extension to higher orders is possible is not clear to us.

In this paper, we have discussed the BPS domain wall. When we construct a realistic brane-world model in a SUSY theory, we must consider the SUSY breaking mechanism. One of the simplest mechanisms of SUSY breaking is the coexistence of the BPS and anti-
BPS walls [16]. In such a case, each domain wall preserves an opposite half of the bulk SUSY, and all of the supersymmetries are broken in the whole system. In the thin wall limit, this corresponds to the one called the pseudo-supersymmetry [19]. The author of Ref. [19] derives the effective theory of the brane-antibrane system by using the non-linear realization technique. In this case, the SUSY breaking effects are induced at loop level because tree-level couplings between the branes are absent. For the wall-antiwall system with a finite wall-width, on the other hand, SUSY breaking appears at tree level although its effects are exponentially suppressed for the distance between the walls [16]. To discuss the phenomenological arguments, it is useful to describe the effective theory on the wall in terms of the superfields and the SUSY breaking terms. Combining the method in Ref. [19] and the result of this paper, we can derive the effective theory in the wall-antiwall system in terms of the 3D superfields and the SUSY breaking terms. This work is now in progress.

A Notations

Basically, we follow the notations of Ref. [20] for the 4D bulk theory. The notations for the 3D theories are as follows.

We take the space-time metric as

$$m_n = \text{diag}(1;1;1;1):$$

(76)

The 3D matrices, $$\{m_{(3)}\}$$, can be written by the Pauli matrices as

$$0_{(3)} = 2; 1_{(3)} = i 3; 3_{(3)} = i 1;$$

(77)

and these satisfy the 3D Clifford algebra,

$$n_{(3)} m_{(3)} n_{(3)} = 2 m_n;$$

(78)

The spinor indices are raised and lowered by multiplying $$\gamma^2$$ from the left.

$$= (2); = (2);$$

(79)

We take the following convention of the contraction of spinor indices.

$$1 \ 2 \ 1 \ 2 = (2) 1 \ 2 = 2 1:$$

(80)
A.1 Covariant derivatives

The algebra of the 3D $N = 1$ SUSY preserved by the wall is

$$f \mathcal{Q}_2 \mathcal{Q}_2 g = 2( \frac{m}{(3)} )^2 P_m :$$

(81)

The representation of the generators on the 3D $N = 1$ superspace $(x^m; \tilde{2})$ is

$$\hat{P}_m = i \Omega_m ;$$

$$\hat{Q}_2 = \Theta_2 + i( \frac{m}{(3)} ) \Theta_m :$$

(82)

The SUSY covariant derivative for $2$ is

$$D_2 \Theta = i( \frac{m}{(3)} ) \Theta_m :$$

(83)

We list the covariant derivatives for superspace coordinates in the presence of the NG super fields as follows. They can be obtained by calculating the Cartan one-form

where is denoted in Eq. (82).

$$D_m 0 = ( -1 )_m \Theta_n 0 = \Theta_m 0 + O ( 1 );$$

$$D_2 0 = D_2 0 + 2_0 i^2 D_2 0 ( \frac{m}{(3)} ) 0 ( -1 )_m \Theta_n 0 ;$$

$$D_m 0 = ( -1 )_m \Theta_n 0 = \Theta_m 0 + O ( 1 );$$

$$D_2 0 = D_2 0 + i^2 D_2 0 ( \frac{m}{(3)} ) 0 ( -1 )_m \Theta_n 0 ;$$

$$D_m = ( -1 )_m \Theta_n = \Theta_m + O ( 1 );$$

$$D_2 = D_2 + i^2 D_2 0 ( \frac{m}{(3)} ) 0 ( -1 )_m \Theta_n ;$$

(84)

where denotes a matter field, and

$$! m_n m + i^2 \Theta_m 0 n ( 3 ) 0 :$$

(85)

A.2 Action of the generators on the fields

The SUSY transformation $^0$ of a chiral super multiplet $(A; ; F)$ is defined by

$$^0 A = P \frac{1}{2} ;$$

$$^0 = i \frac{1}{2} ( ) A + P \frac{1}{2} F ;$$

$$^0 F = i \frac{1}{2} :$$

(86)

We define an action of the generators $P$, $Q$ and $Q^-$ on the fields $= A; ; F$ as

$$P : i \Theta ;$$

$$( Q + Q ) :$$

(87)

Under the above definition, the chiral super field can be written as

$$(x; ; ) = e^{i x^P + Q^+ Q} A(0);$$

(88)
There is a useful formula that converts covariant derivatives $D_M$ into the corresponding generators $\mu$.

$$D_M e^{iX^\mu} = e^{iX^\mu} M_\mu;$$

(89)

where $X^\mu$ are coordinates for $\mu$.

For the SUSY generator $Q_2$, for instance,

$$D_2 e^{iX^\mu} P_\mu + iQ_2 = e^{iX^\mu} P_\mu + iQ_2 Q_2;$$

(90)

Using this formula, we can rewrite the chiral condition for as follows.

$$D_-= D_- e^{Q^+ Q} A(x) = e^{Q^+ Q} A(x) = 0;$$

(91)

Then,

$$Q_- A(x) = \frac{e^{i=2}}{2} (Q_1 + iQ_2) A(x) = 0;$$

(92)

Namely,

$$Q_1 A = iQ A;$$

(93)

B Bosonic part of $S_{NG}$

Here we will provide a brief derivation of the Nambu-Goto action from the effective action $S_{NG}$ defined in Eq. (13). We denote the component fields of $\phi_0$ as

$$\phi_0 = a_0 + \frac{1}{2} x_0 + \frac{1}{2} f_0;$$

(94)

In order to concentrate on the bosonic part of $S_{NG}$, we will neglect the fermionic component $\phi_0$ in the following. Then,

$$D_2 (2\phi_0) = \frac{1}{4} (f_0^2 + 2a_0 \partial_m a_0);$$

(95)

and

$$D_2 (2\phi_0) = \frac{1}{4} (f_0^2 + 2a_0 \partial_m a_0);$$

(96)

Therefore, the auxiliary field $f_0$ enters in $S_{NG}$ only in a bilinear way. This means that an equation of motion for $f_0$ is $f_0 = 0$. Hence, after the elimination of $f_0$, the bosonic part of $S_{NG}$ becomes

$$S_{NG}^{bosonic} = \frac{1}{2} \int d^3x \left[ a_0 \partial_m \partial_m a_0 \right];$$

(97)

This is the Nambu-Goto action in the static gauge, as expected.
C Transformation of \( i \) under the broken symmetries

The transformation laws of \( i \) for the broken symmetries are obtained from the definition of \( i \) in Eq. (32) and the SUSY algebra (1).

For example, for the \( Q_1 \)-transformation,

\[
Q_1^i = 1 Q_1 e^{i \kappa P_n + i \omega P_2 + i \eta Q_2} A^i(0)
\]

\[
e^{i \kappa P_n + i \omega P_2 + i \eta Q_2} (2i_1 2P_2 + i_1 Q_1) A^i(0)
\]

\[
e^{i \kappa P_n + i \omega P_2 + i \eta Q_2} (2i_1 2P_2 - i_1 Q_1) A^i(0)
\]

\[
= (2i_1 2Q_2) A^i(0)
\]

Here we have used the chiral condition Eq. (93) and the formula Eq. (89).

Similarly, for the \( P_2 \)-transformation,

\[
P_2^i = i a P_2 A^i(0)
\]

\[
= a @_2 A^i(0)
\]

For the broken Lorentz transformation,

\[
K_{\nu}^i = \eta^n K_m \rightharpoonup_{\nu}^i = \eta^n x_2 @_{\nu}^i = x_2 @_{\nu}^i + \frac{1}{2} \eta^{(3m D_2}^i
\]

For the \( U(1) \)-transformation,

\[
R^i = i \eta R \rightharpoonup_{R}^i = \eta^{(3m D_2}^i + i \eta D_2^i
\]

D In the case of \( G = G_{\text{max}} \)

Here we collect the main results of the nonlinear realization in the case that the full symmetry group \( G \) is taken to be \( G_{\text{max}} = f P_m ; P_2 ; Q_1 ; Q_2 ; M_{mn} ; K_{m} ; R_{g} \). The vacuum stability subgroup is \( H_{\text{max}} = f P_m ; Q_2 ; M_{mn} g \) in this case.

D.1 Super-Poincare algebra

The 3D \( N = 2 \) super-Poincare algebra with central extension is as follows.

\[
f Q_1 ; Q_1 = f Q_2 ; Q_2 = 2(\frac{m}{3})^2 P_m ;
\]

\[
f Q_1 ; Q_2 = f Q_2 ; Q_1 = 2i l (\frac{2}{3}) P_2 ;
\]

\[
[M_{mn} ; Q_1 ] = i (\frac{3m}{n} Q_1 ; [ M_{mn} ; Q_2 ] = i (\frac{3m}{n} Q_2 ;
\]

\[
[K_m ; Q_1 ] = \frac{1}{2} (\frac{3m}{3} Q_2 ; [ K_m ; Q_2 ] = \frac{1}{2} (\frac{3m}{3} Q_1 ;
\]

\[
[R ; Q_1 ] = i Q_2 ; [ R ; Q_2 ] = i Q_1 ;
\]

\[
[M_{mn} ; P_1 ] = i (\frac{m}{3} P_n - \frac{m}{3} P_m ) ; [ M_{mn} ; P_2 ] = 0
\]
\[
\begin{align*}
[K_m; P_n] &= i m n P_2; \quad [K_m; P_2] = i P_m ;

[M_{m n}; P_0] &= i ( m _{m n p} n M_{m p} - p n M_{m n} + p m M_{l n} );

[M_{m n}; K_1] &= i ( m _{m n p} n K_{n} - n K_{m} );

[K_m; K_n] &= i M_{m n} ;
\end{align*}
\] (102)

D.2 Standard non-linear transformations

A coset element can be parametrized as

\[
^\wedge = e^{i\theta_0 P_0} e^{i\theta_1 P_2} e^{i\chi K_0} e^{i\chi K_0};
\] (103)

where \(\theta_0\), \(\theta_1\), \(\chi\) and \(\chi\) are the NG super fields for the corresponding generators.

The transformation laws of each super field are obtained by multiplying \(^\wedge\) by corresponding group elements from the left.

For \(P_2\)-transformation,

\[
\begin{align*}
P_2 a 0 &= 1 a ;

P_2 a 0 &= P_2 m a 0 = P_2 0 a 0 = P_2 a 0 = 0;
\end{align*}
\] (104)

For the broken SUSY,

\[
\begin{align*}
Q_1^{(1)} 0 &= 2 1 2 11 m (3) 0 \theta_m 0 ;

Q_1^{(1)} 0 &= 1 1 1 m (3) 0 \theta_m 0 ;

Q_1^{(1)} m 0 &= 1 1 n (3) 0 \theta_n m 0 ;

Q_1^{(1)} 0 &= 1 1 m (3) 0 \theta_m 0 ;

Q_1^{(1)} 1 &= 1 1 m (3) 0 \theta_m 0 ;
\end{align*}
\] (105)

For the broken Lorentz symmetry,

\[
\begin{align*}
K v 0 &= \frac{1}{2} \nu^m x_m + O ( ) ;

K v 0 &= \frac{1}{2} \nu^m (3m 2) + O ( ) ;

K v 0 &= \nu^m + O ( ) ;

K v 0 &= O ( ) ;

K v 0 &= \nu^m 0 + \frac{1}{2} n (3m 2) \theta_n + \frac{1}{2} 0 (3m D 2) ;
\end{align*}
\] (106)

For the U(1)_R symmetry,

\[
\begin{align*}
R r 0 &= r 1 2 2 0 1 m (3) 2 \theta_m 0 0 D_2 0 ;

R r 0 &= r 1 2 0 1 m (3) 2 \theta_m 0 0 D_2 0 ;

R r 0 &= r 1 0 n (3) 2 \theta_n m 0 0 D_2 0 ;

R r 0 &= r 1 0 m (3) 2 \theta_m 0 0 D_2 0 ;

R r 0 &= r 1 0 (3) 2 \theta_m 0 0 D_2 :
\end{align*}
\] (107)
Here, $a, v^m$ and $r$ are transformation parameters, and $\mathbf{1}$ denotes a matter field.

### D.3 Inverse Higgs effect

The NG super fields introduced in Eq. (103) are not independent. The relation between them are obtained by the following covariant constraints [13,21].

$$D^2_0 = 0; \quad D^2_m = 0; \quad D^m_0 = 0:$$

(108)

Here $D^m_0$ and $D^2_m$ are covariant derivatives in the presence of the NG super fields, which are derived from the Cartan one-form $^1d^a$.

Solving these constraints, we can express all NG super fields in terms of a single super field $\mathbf{1}$.

$$0 = \frac{1}{2} D^2_0 + O(\delta^2);$$

$$m = 0 = \frac{1}{2} D^2_0 + O(\delta^2);$$

$$0 = \frac{1}{2} D^2_0 + O(\delta^2);$$

(109)
