We study the possible e ects of TeV scale new physics (NP) on the rate for Higgs boson decays to charged leptons, focusing on the + channel which can be readily studied at the Large Hadron Collider. Using an SU(3) × SU(2) × U(1) invariant effective theory valid below a NP scale , we determine all effective operators up to dimension six that could generate appreciable contributions to the decay rate and compute the dependence of the rate on the corresponding operator coefficients. We bound the size of these operator coef cient based on the scale of the mass, naturalness considerations, and experimental constraints on the anomalous magnetic moment. These considerations imply that contributions to the decay rate, when TeV, could be comparable to the prediction based on the SM Yukawa interaction. A reliable test of the Higgs mechanism for fermion mass generation via the channel is possible only after such NP e ects are understood and brought under theoretical control.

I. INTRODUCTION

The search for the Higgs boson and the study of its properties is a primary task of the Large Hadron Collider (LHC). Currently, global fits to precision electroweak data and the Higgs mass are to be 84 ± 3.2 GeV with an upper bound given by m_h < 150 GeV at 95% CL [1]. Collider has also placed a lower bound of m_h > 114.4 GeV [2]. A summary of the Standard Model (SM) of electroweak interactions, the Higgs is expected to be found in early physics runs at LHC or in the near future at the Tevatron.

If a new scalar particle is found at LHC or the Tevatron, studying its self-coupling and its couplings to fermions and gauge bosons will be important steps in determining whether or not it is the SM Higgs boson. One promising channel for testing the coupling to fermion is h + [3]. One can look at Higgs production via Weak Boson Fusion (WBF) which has distinctive signals (see [4] for a general review, see [5] for NP e ects on WBF) allowing one to eliminate most of the QCD background. In addition, in WBF the Higgs is typically produced with p_T > 100 GeV m which facilitates a relatively precise invariant mass reconstruction of the + pair. Realistically, at the LHC a measurement of the h + coupling for m_h < 140 GeV is expected to be made with about 100 fb^(-1) of data to 10% accuracy[6,7].

In this paper, we examine how new physics (NP) at or above the TeV scale could e ect the decay rate (h + ). If such e ects are large, they could complicate a test of the SM Higgs mechanism for fermion mass generation using this decay channel. Of course identical statements can be made for h ! e+ e− although these channels are too suppressed by small Yukawa couplings to be experimentally interesting (we will brie y comment on these particular channels). In order to analyze possible NP e ects on (h + ) in a model-independent manner, we employ an effective field theory approach where NP e ects are encoded in SU(3) × SU(2) × U(1) invariant higher dimension operators built out of SM fields:

\[ L_e = \sum_n \frac{C^n_j}{4} O^{(n)}_j(\phi) + \text{h.c.} \tag{1} \]

where \( C^n_j \) is renormalization scale, \( n \geq 4 \) denotes the operator dimension, and \( j \) is the index running over all independent operators.

In what follows, we will take the NP scale to be at or above the TeV scale. New physics at such a scale...
is expected for at least two reasons: triviality asserts that the Higgs mass vanishes in the absence of a cut off \( \mathcal{O} \), and the radiative instability in the Higgs sector in the absence of additional NP leads to the hierarchy problem. Such an EFT approach, with \( \text{TeV} \), has been applied to precision electroweak observables [1, 10, 11, 12, 13, 14] and has recently been the subject of further investigations for LHC and ILC phenomenology [15, 16, 17, 18, 19, 20, 21, 22, 23] as well as neutrino properties and interactions [22, 23, 24, 25].

We use naturalness and/or experimental constraints to bound the Wilson coe cients of the relevant higher dimension operators. We nd for \( h'\) where \( ^{'} = e; \), \( y \), that \( ( h ! ^{'} ' ') = ( \text{SM} + \text{NP} \text{SM}) = \text{SM} \sqrt{\gamma^2 = 1 - y \ C, \text{where } y = 246 \text{ GeV} \text{is the Higgs vacuum expectation value }, y \text{ the charged lepton Yukawa coupling, and } C \text{ denotes a combination of } W \text{ and Higgs coe cients of the higher dimension operators.} \)

Given that \( 1 = y \cdot 1 \), one might naively expect that very large deviations from the SM rate could be observed. As we show, naturalness considerations generally imply that \( C \), \( y \), thereby counteracting the \( 1 = y \cdot \text{enhancement. } \text{Nevertheless, when } y \text{ is not too large compared to } v \text{, we nd that } \gamma \text{ can be of order unity. In this case, a reliable test of the Higgs mechanism for lepton mass generation would require additional studies to disentangle the e ects of NP in the } h' \text{ channel.} \)

II. HIGHER DIMENSION OPERATORS

The lowest dimension operator that contributes to \( h' \) is \( n = 4 \text{ SM Yukawa interaction} \)

\[
y.y.O_{eY} + h.C.; \quad O_{eY} \quad L \ e
\]

where \( L \) and \( e \) are lepton \( SU(2)_L \), doublet and right handed charged lepton singlet eL and \( eR \) respectively and is the Higgs doublet\(^1\). The e ects of new physics rst appear at \( n = 6 \). Since \( \text{TeV} \), contributions from \( n > 6 \) operators can be safely omitted. Using the basis of Buchmuller and Wyler [22], the operators relevant to the \( h'' \) channel at tree level are

\[
\begin{align*}
O_{eH} &= (y) L e; \\
O_{H}^{(1)} &= i(yD \downarrow) (L \ L); \\
O_{H}^{(3)} &= i(yD \uparrow) (L \ \downarrow L); \\
O_{D} &= i(yD \downarrow) (e \ e); \\
O_{D} &= L (D \ D \ e; \\
O_{D} &= L D Y \downarrow (D \ e): \\
%
\end{align*}
\]

It is also useful to consider the symmetric and antisymmetric combinations of the last two operators in Eq. (3)  

\[
O = L (D \ D \ e \ L D Y \downarrow (D \ e); \quad (4) 
\]

It is straightforward to show that the symmetric combination \( O_+ \) can be expressed as linear combination of \( O_{eH}, O_{eH} \), and four fermion operators to use nonanomalous and the scalar potential \( V_h(\ ) \) is given by

\[
V_h(\ ) = m^2 y + \frac{y^2}{2} ; \quad (6)
\]

The total derivative on the LHS of Eq. (6) yields a vanishing contribution to the action associated with \( L_e \), so one can eliminate \( O_+ \) in terms of the other operators appearing on the R.H.S. For purposes of this analysis, it is convenient to eliminate one of the four-fermion operators appearing in Eq. (6) and to retain both \( O_{eH} \) and \( O_+ \) explicitly.
III. n = 6 Contributions to h " " Decay

Contributions to (h ! " " ) can be obtained by expanding the Higgs field as usual around its vacuum expectation value v, so that

\[ \langle x \rangle = \frac{U(x)}{2} v + h(x). \] (7)

Here \( U(x) = e^{i \cdot \cdot \cdot (x) \cdot \cdot \cdot v} \) and \( v(x) \) are the Goldstone boson fields. In unitary gauge \( U(x) = 1 \) and all couplings to the Goldstone bosons vanish. In general, we consider only contributions to \( h \) that are linear in the \( n = 6 \) operator coefficients and that contain one power of \( v^2 = 2 \). Such terms can only arise from the interference of the SM Yukawa amplitude for the decay with the corresponding amplitudes generated by one of the \( n = 6 \) operators.

Because the operators \( O_{H}^{(1,2)} \) and \( O_{H} \) contain only same chirality lepton fields, they cannot interfere with \( O_{\mu \tau} \). Consequently, their contributions will appear at \( O (v^2 = 4) \), as we have verified by explicit computation. The \( O (v^2 = 2) \) terms, therefore, are generated by \( O_{\mu \tau} \), \( O_{\mu \mu} \), and \( O_{\mu \tau} \) whose amplitudes interfere with \( O_{\mu \tau} \). We also observe that only the symmetric combination \( O_{s} \), contributes at \( O (v^2 = 2) \) since \( O_{\mu \tau} \) can be written as a linear combination of the magnetic moment operators that do not contribute to the decay rate and the \( n = 6 \) operators whose effects are chirally suppressed (see below). Thus, we need to consider only the effects of two operators: \( O_{\mu \tau} \) and \( O_{\mu \tau} \).

Computing the shifts from these two operators is a straightforward exercise. The relevant Feynman rules for \( O_{\mu \tau} \) are identical to those for \( O_{\mu \tau} \) up to the overall difference in operator coefficients. For \( O_{\tau} \), we exploit Eq. (3) to relate it to \( O_{\mu \tau} \) and \( O_{\mu \tau} \), and the four fermion operators that do not contribute to the tree-level. The corresponding Feynman rules for \( O_{\tau} \) can then be obtained by the appropriate combination of those for the Yukawa interaction and \( O_{\mu \tau} \). Thus, we have

\[ y \cdot O_{\mu \tau} + \frac{v_{\mu}^{2}}{2} P_{R} \cdot h; \]

\[ C_{\mu \tau} \cdot O_{\mu \tau} + \frac{3C_{\mu \tau} v^{2}}{2} P_{R} \cdot h; \] \hspace{1cm} (8)

\[ C_{\tau} \cdot O_{\tau} + \frac{3C_{\tau} v^{2}}{2} \cdot \frac{3m_{h}^{2} + 2m_{\mu}^{2}}{2} P_{R} \cdot h; \]

\[ \cdot \frac{C_{\tau} m_{\mu}^{2}}{2} P_{R} \cdot h; \]

where \( \tau \) is the charged lepton field, \( P_{R} \) is the right-handed projection operator and where, in the obtaining the last line of Eq. (3), we have used the conditions for EW SB to relate \( m_{\mu}^{2} \) and \( v^{2} \) to the Higgs mass squared \( m_{h}^{2} \).

The contribution from \( O_{\mu \tau} \) and \( O_{\tau} \), can be read off from Eq. (3) by using the SM rate

\[ (h ! " " )_{SM} = \frac{y_{\mu \tau}^{2} m_{h}}{16} 1 \cdot \frac{4m_{\mu}^{2} + m_{h}^{2}}{3} = \frac{3}{2} ; \] \hspace{1cm} (9)

and replacing \( y \cdot y_{\mu \tau} + 3C_{\mu \tau} v^{2} = 2 + \frac{C_{\tau} m_{h}^{2}}{2} \), where \( y_{\mu \tau} \) denotes the coefficient of \( O_{\mu \tau} \) in the presence of NP. In general, the appearance of a higher-dimension operator that contributes to the lepton mass will change the relationship between the Yukawa coupling and \( m_{\mu} \), implying that \( y_{\mu} \sim y_{\tau} \). In the SM, this relationship is

\[ y_{\mu \tau} = \frac{P_{R} m_{\mu}}{v}; \] \hspace{1cm} (10)

For the \( n = 6 \) operators considered here, \( O_{\mu \tau} \) generates a tree-level contribution to \( m_{\tau} \). In this case, Eq. (10) no longer gives the relationship between the lepton mass that appears in the Lagrangian density after EW SB and the coefficient \( y_{\mu \tau} \), and we must replace it by

\[ y_{\mu} = y_{\mu \tau} + y_{\mu \tau} \; ; \] \hspace{1cm} (11)

where \( y_{\mu \tau} \) is given by its SM value as in Eq. (10) and \( y_{\mu \tau} \) gives the shift due to the presence of a non-vanishing \( C_{\mu \tau} \). In contrast, the \( O_{\mu \tau} \) contributes to \( m_{\mu} \), only at the

\[ \cdot \frac{C_{\tau} m_{\mu}^{2}}{2} P_{R} \cdot h; \]

\[ \cdot \frac{C_{\tau} m_{\mu}^{2}}{2} P_{R} \cdot h; \]

\[ \cdot \frac{C_{\tau} m_{\mu}^{2}}{2} P_{R} \cdot h; \]

\[ \cdot \frac{C_{\tau} m_{\mu}^{2}}{2} P_{R} \cdot h; \]

2 In some instances, however, the naturalness considerations discussed below imply NP contributions to of the same size as the SM rate, and we retain the quadratic terms in these cases.

3 We thank Mark Wise for pointing out the need to include this correction.
one-loop level through its mixing with $O_{\text{eff}}$ and the effects of matching onto $O_{\text{Mix}}$ at the scale (see below). In this case, the mixing of $O_{\text{Mix}}$ with $O_{\text{eff}}$ implies a non-vanishing $y$. 

The resulting expression for the relative change in the decay rate is

$$
\frac{h !}{h !} \sim \frac{(y + a_y v^2) - y}{y^2} = 1 \quad (12)
$$

where

$$
a_y = \frac{3}{2} \frac{C_{\text{eff}}}{v^2} + \frac{m_y^2}{v^2} C_e ; \quad (13)
$$

where we have taken all operator coefficients to be real for purposes of this analysis.

To the extent that the effects of $O_{\text{eff}}$ and $O_{\text{Mix}}$ on $m_h$ and are suppressed by $v^2$, we may write Eq. (12) as

$$
\frac{h !}{h !} \sim \frac{(y + a_y v^2) - y}{y} = 1 + O \left( \frac{v^4}{v^2} \right) \quad (14)
$$

and we have used $C_e = (C_{D_e} + C_{D_e})/2$. We have cross-checked the result in Eqs. (13)(14) by using the operators $O_{D_e}$ and $O_{D_e}$ directly without employing the equations of motion while noting that $C_e = (C_{D_e} + C_{D_e})/2$.

We observe that the contribution from $O_{\text{eff}}$ depends on $v^2$, while the effect of $O_{\text{Mix}}$ varies as $m_h^2 = v^2$. For the $h !$ channel, we obtain

$$
\frac{h !}{h !} \sim \frac{(y + a_y v^2) - y}{y} = 200 \quad (15)
$$

indicating the possibility of significant NP effects at a TeV and reasonable choices for the Wilson coefficient. We will explore bounds on the size of the Wilson coefficients in later sections and show that naturalness considerations imply that they are generally proportional to $y$.

IV. ESTIMATES OF NP EFFECTS ON h !’’

The expressions in Eq. (12)(14) allow us to estimate the size of possible new physics contributions to the $h !’’$ rate. As discussed in Ref. [23], the operators $O_{\text{eff}}$, $O_{D_e}$, and $O_{D_e}$ could be generated by tree level effects of new physics above the scale. As a result, the corresponding operator coefficients could in principle be $O(1)$ rather than $O(16^2)$ as in a naive application of naive dimensional analysis (NDA) [29]. Setting $v^2 = (2y)^2 = 1$ one finds that NP can have an $O(1)$ effect for $v < 3$ TeV for $’-$, $v < 12$ TeV for $’-$, and $v < 170$ TeV for $’-$.

The resulting shifts are quite large unless $y$ is very large compared to $v$ and $m_h$. However, because these operators have the same chiral structure as $O_{\text{Mix}}$, their coefficients are likely to be constrained by the scale of the charged lepton mass in the absence of large cancellations between the effects of different operators. In this section we discuss these “naturalness” constraints as well as those following from other chirality changing operators such as the charged lepton magnetic moment. We show that $O(1)$ corrections to the SM decay rate are still possible.

We will determine the naturalness expectations for the magnitudes of $C_{\text{eff}}$ and $C_e$ separately. In any specific NP scenario, the values of these coefficients at the scale are determined after integrating out the heavy degrees of freedom. The resulting terms in $L_e$ (1) $C_{\text{eff}}$, $(O_{\text{eff}} = 2$ and $C_e$) $(O_{\text{Mix}} = 2$ will generate contributions to the charged lepton mass after evolving to the appropriate low scale. We will assume that the magnitudes of these contributions are no larger than the magnitude of the charged lepton mass itself. To determine the corresponding contributions to $’-$, we use the full expression in Eq. (12) since the $O(y^2)$ term $s$ (and in some cases, the $O(a_y^2)$ terms) are not necessarily negligible. We also analyze these effects for both choices for the phase of $C_{\text{eff}}$ and $C_e$ and generally quote the most restrictive result as the corresponding naturalness expectation.

In deriving the resulting naturalness expectations for the $n = 6$ operator coefficients, we will follow the approach used recently in Refs. [24, 25, 26, 27] to derive constraints on operators relevant to neutrino properties.
and low-energy weak decays based on the scale of neutrino mass. In doing so, we consider three ways in which the presence of a non-zero $C_{\text{eff}}$ or $C_{\text{eff}}$ at the high scale can contribute to $m$.

(i) Through tree-level contributions of the corresponding operator.

(ii) Through one-loop contributions to the $n = 4$ lepton mass operator, $O_{\text{eff}}$ at the high scale.

(iii) Via one-loop mixing of the $n = 6$ operators that depend on $m_\text{cm}$ mediator between the electroweak scale. Below the EW scale our effective theory must be matched onto a different effective theory in which the $W$ and $Z$ have been integrated out. The constraints that follow from the latter low-energy effective theory are too weak to be interesting.

Although the naturalness considerations can be applied to constrain $h ! " = f e$; $g$, we will focus on the phenomenologically more interesting $h ! "$ channel.

A. Naturalness constraints on $O_{\text{eff}}$

The analysis of naturalness considerations for $O_{\text{eff}}$ is particularly straightforward, as it generates a tree-level contribution to $m$

\[ m [O_{\text{eff}}] = \frac{C_{\text{eff}}(z)}{2z} v^2 : \quad (16) \]

Here, we have omitted corrections associated with the running of $C_{\text{eff}}(z)$ from the scale $\mu$ to $z$ as they are loop and coupling suppressed and do not substantially affect the corresponding naturalness expectation. In the absence of large cancellations between this contribution and SM Yukawa contribution, we have $j m j < m$

\[ \sum_{\text{eff}}(z) j \leq 2 y : \quad (17) \]

The resulting shift in the Yukawa coupling is $y = y (y)$ for positive (negative) $C_{\text{eff}}$. Using Eq. (17) we obtain the naturalness bounds $= 8 \ (= 0)$. It is interesting to note that these bounds are lepton species-independent since the RHS of Eq. (17) is proportional to the Yukawa factor, thereby canceling the factor of $y^2$ in the denominator of Eq. (17).

When $v$, the upper bound on $\sum_{\text{eff}} j^2 = 2$ Eq. (17) can allow the magnitude of the operator coefficient to be much larger than unity. In addition to appearing physically unreasonable, the presence of very large effective operator coefficients invalidates the truncation of the expansion in Eq. (17) at any order. Consequently, we do not consider Eq. (17) to be physically meaningful for $v$. A more stringent expectation for the possible magnitude of $C_{\text{eff}}$ can be derived for large (see below) by considering the effects of $O_{\text{eff}}$ at one-loop order. Effects of loop $m_{\text{cm}}$ enantiomorph can also generate contributions from $O_{\text{eff}}$ to the $n = 4$ Yukawa interaction $O_Y$ as in Fig. 1:

**Fig. 1:** The one-loop contribution of $O_{\text{eff}}$ to $O_Y$.

These contributions will appear when the full theory above the scale is used to compute renormalization of $O_{\text{eff}}$ and, thus, would generate a matching correction to the effective theory below the scale. Without knowing the full theory, we cannot compute this matching contribution precisely. Nevertheless, it is possible to estimate its magnitude using NDA. Doing so yields

\[ m [O_{\text{eff}} \ O_Y] \frac{C_{\text{eff}}(z)}{16} \frac{3v}{2} : \quad (18) \]

leading to

\[ \sum_{\text{eff}}(z) j < \frac{16}{3} y : \quad (19) \]

The resulting expectation for the possible size of $= \ldots$
becomes more stringent than the tree-level bound when $v > 4 \sqrt{2}$ since the corresponding contribution to the RHS of Eq. (13) decreases as $v^2$. It is possible that details of a specific model for NP above the scale will preclude any contributions from $O_{\text{eff}}$ to $O_{\text{eff}}$, in which case the naturalness expectation in Eq. (15) would not apply. In the absence of such a specific scenario, however, Eq. (15) gives a reasonable estimate of the magnitude of $C_{\text{eff}}$.

We illustrate the expectations for $C_{\text{eff}}$ obtained from Eqs. (15) and (17) in Fig. 2.

![Fig. 2: Combined tree and loop level naturalness bounds on $C_{\text{eff}}$ arising from $O_{\text{eff}}$. The region between the curve and the x axis is the space of allowed $C_{\text{eff}}$ due to naturalness constraints. The result shown is for $y = y_1$.](image)

Under renormalization, $O_{\text{eff}}$ will mix with other $n = 6$ operators, including $O_{D \, e}$ and $O_{D \, e}$ as in Fig. 4. This mixing among like-dimension operators is sensitive to loops coming from the scale to the scale associated with the physical process. In the case of $O_{\text{eff}}$, these one-loop mixing effects are dominated by operator self-renormalization, yielding a small correction to the tree-level bound in Eq. (17).

B. Naturalness constraints on $O_{\text{eff}}$.

We first observe that $O_{\text{eff}}$ does not contribute to $m$ at tree-level since it contains a covariant derivative acting on $\phi$. Immediately, we can express Eq. (4) as

$$\theta \; \mathcal{L} \stackrel{0}{(D \; e)} = \mathcal{L} \frac{V_{H_i}}{\Lambda} e + O_{\text{eff}} \tag{20}$$

$$\mathcal{L} \frac{V_{H_i}}{\Lambda} e + \mathcal{L} \frac{y_1 (L \, b \, e) (q_{\mu} \, u \, u)}{\Lambda} \tag{21}$$

so that $O_{\text{eff}}$ can be expressed as a linear combination of four fermion operators that do not contribute to $m$ at tree level and

$$L \frac{V_{H_i}}{\Lambda} e : \tag{21}$$

Since the condition for EW SB is given by $V_{H_i} = = 0$, $O_{\text{eff}}$ does not contribute to $m$ at tree level. At one loop order, $O_{\text{eff}}$ generates contributions to both $O_{\text{eff}}$ and $O_{\text{eff}}$. Illustrative, one-loop matching contributions are shown in Fig. 3. The EW loops give naturalness constraints proportional to $y$ while the Higgs loops give far weaker constraints proportional to $1-y$. The strongest constraints are dictated by the strongest effective coupling in the EW sector. Since we cannot determine the precise numerical coefficient on the RHS of Eq. (22) we have estimated the matching contribution using only the SU(2)$_L$, gauge loops, neglecting the U(1)$_Y$ and Yukawa-suppressed Higgs loop effects. Since we are only interested in order-of-magnitude expectations, this is sufficient. We again use NDA and obtain

$$m \left[ \frac{1}{6} \right] \frac{C_{\text{eff}}(\frac{\Lambda}{16})}{\Lambda} \frac{V_{H_i}}{\Lambda} e + O_{\text{eff}} \tag{22}$$

5 The effects of the $O_{\text{eff}}$ operator on higgs Yukawa couplings has been recently studied within the context of multi-scalar doublet models in [8]. Large regions of parameter space were found where order one effects are realized in the higgs decay rate in agreement with the large effects found to be possible in our naturalness bounds.
leading to

$$\mathcal{J}_e ( \gamma ) < 4 \sin^2 \frac{\gamma}{2} \quad : (23)$$

The mixing with $O_{\text{eh}}$ is given to lowest order in the lepton Yukawa coupling by the diagrams in Fig. 4. In principle, one can obtain this mixing by computing the anomalous dimension matrix for $O_{\text{eh}}, O_+,$ and any other independent $n = 6$ operators that mix under renormalization and solving the corresponding renormalization group equations. For the purposes of deriving order-of-magnitude naturalness constraints it suffices to keep only the leading logarithmic contributions (see, e.g., Refs. 24, 25, 26, 27) which we have computed. The contribution to the Wilson coefficient of $O_{\text{eh}}$ from $O_+$ via mixing is given by

$$C_{\text{eh}} ( \gamma ) = C_+ ( \gamma ) \sim \ln \gamma + \quad : (24)$$

and the dots above denote contributions from self renormalization and the mixing of other operators into $O_{\text{eh}}$. We obtain $\gamma$ from the one loop computation of the diagrams in Fig. 4, we find

$$\gamma = \frac{1}{16} \left( 3 g_1^4 + \frac{9 g_1^4}{8} + \frac{9 g_2^4}{2} \right) \quad : (25)$$

Requiring that the resulting contribution to the mass be of the same order of magnitude as, or smaller than, the lepton Yukawa coupling by the diagrams in Fig. 4.

FIG. 4: The one-loop contribution of $O_+$ to $O_{\text{eh}}$. The dashed lines are $W$-bosons, the wiggling lines are the SU(2) and U(1) gauge bosons. Note that we are above the EW scale $v$.

Substituting this inequality into Eq. (22) leads to an upper bound on the contribution from $O_+$ to $h^+$ that decreases logarithmically as increases but grows quadratically with $m_h$. This bound is generally weaker than the expectation based on one-loop matching, but it will apply even in specific models that give a negligible renormalization of $O_{\text{eh}}$.

Before looking at the implications of the above naturalness constraints on the bounds for $h^+$, in the next section we explore possible constraints arising from the measurement of the anomalous magnetic moment.

C. Anomalous magnetic moment constraints on $O_+$.

Since the coefficients $C_+ ( \gamma)$ of $O_+$ depend on linear combinations of $C_{\overline{O}}$ and $C_{\overline{O}}$, one might expect $C_+ ( \gamma)$ in any NP scenario that gives rise to both operators. While $O_+$ does not contribute to $h^+$ at tree-level, it does contribute to the anomalous magnetic moment. Specifically, $O_+$ can be expressed in terms of the magnetic moment operators

$$O_B = g_1 L^1 e_B \quad : (27)$$
$$O_W = g_2 L^1 e_W \quad : (28)$$
and $O_{H,e}$ and $O_{H}^{(1)}$ by using the identity
\[ D^2 = H^2 + i D^2 \] (29)
and suitable integrations by parts, leading to
\[ O + h:\ = \frac{1}{4} (Y_L + Y_e) O_B + \frac{1}{4} O_W \]
\[ \times O_{H,e} + y_e O_{H}^{(1)} + h:\ ] (30)
After EW SB, one has
\[ O_B \rightarrow \frac{g_B v^2}{2} \frac{g_B v^2}{2} \left[ \sin \theta Z + \cos \theta F \right] \] (31)
\[ O_W \rightarrow \frac{g_W v^2}{2} \frac{g_W v^2}{2} \left[ \cos \theta Z + \sin \theta F \right] \]
where $F$ and $Z$ are the field strength tensors for the $Z^0$ and photon respectively. Since $g_i \cos \theta = g_2 \sin \theta = e$, we have
\[ \frac{1}{2} [O_B + h:\] \left[ \frac{v^2}{2} \right] = \frac{e}{4m} \left[ \theta \right] F \] (32)
Using this result, together with Eq. (30) and the definition of the anomalous magnetic moment $a$,
\[ a = \frac{g_2}{2} \] (33)
as the coefficient of the operator
\[ \frac{e}{4m} \left[ \theta \right] F \] (34)
we obtain
\[ a [O] = 2 \frac{v^2}{2} y e \left[ \sin \theta \right] C \] (35)
The anomalous magnetic moment has never been directly measured. The best bound is given by DELPHI [31] which finds the 95% CL
\[ 0.052 < a < 0.013 \] (36)
The current standard model calculation [32] of $a$ is
\[ a = 117721(5) \times 10^{-8} \] (37)
This leads to a conservative estimate of the deviation from the SM, considering the lack of data, given by
\[ a < 1 \times 10^{-3} \] (38)
Using this bound and Eq. (33) leads to
\[ \frac{v^2}{2} < 0.05 \] (39)
If NP at high scales leads to
\[ f D o f D o + f D o + f D o + f D o + f D o \] (40)
then Eq. (35) would imply an upper bound on the contribution from $O_{H}$ to $a$.

### C. Combined Constraints

![Combined Constraints Graph](image)

**Fig. 5:** The combined constraints on contributions from $O_{H}$ due to (1) the anomalous magnetic moment constraint on $C_{1}$ in the NP scenario where $f D o f D o + f D o + f D o + f D o + f D o j$ and (2) the naturalness constraint on $O_{H}$ due to the one-loop matching contribution to $O_{H}$ from $O_{W}$. In both cases we have set $m_{h} = 140 \text{ GeV}$.

In Fig. 5, we plot the bound on the contribution of $O_{H}$ to $a$ as a function of the NP scale for the choice $m_{h} = 140 \text{ GeV}$. The curved solid line comes from the naturalness bound in Eq. (33) and the horizontal solid line comes from the magnetic moment constraint of Eq. (39). As seen in this gure, the $m_{h}$ naturalness bounds dominate at higher values of the NP scale. Only for lower values of the NP scale $< 1 \text{ TeV}$ do the magnetic moment constraints become important for $h$. It is also possible for $h$ above to dictate $f D o f D o j$ since $O_{H}$ and $O_{W}$ are independent operators. In this case the constraints from $a_{H}$ on $C_{1}$ will not apply to $C_{1}$ even for $< 1 \text{ TeV}$.

It is also interesting to consider the Higgs mass dependence of the contribution of $O_{H}$ to $a$ for a fixed value of $\Lambda$. This is shown in Fig. 5 for $\Lambda = 1.3 \times 10^{-8} \text{ TeV}$ where
The corresponding constraint in this case will be

$$ C \frac{v^2}{2} < 2 \times 10^4; \quad (42) $$

from which we conclude a possible 20% effect in $(h ! ^+ )= . This is due to an enhancement coming from two Yukawa factors. The first Yukawa factor appears in the standard way as shown in Eq.(13). An additional Yukawa factor appears as seen in Eq.(35) which dictates the bound on $C$ due to the anomalous magnetic moment constraint. These two enhancements give $= 1 = y^2$ allowing for a sizable effect. For this reason, realistic future in provenents in the measurement of the anomalous magnetic moment are unlikely to severely constrain $(h ! ^+ )= .$

V. IMPLICATIONS AND CONCLUSIONS

Without a specific model for NP whose low-energy effects are characterized by the $n = 6$ effective operators, we cannot make precise quantitative predictions for $= . It is, nevertheless, possible to identify four possible scenarios that could result from integrating out the massive degrees of freedom and estimate the size of their effects using naturalness criteria consistent with experimental constraints. From the standpoint of $h ! ^+$ decays, these scenarios can be described in terms of the operators $O_{\text{eff}}$ and $O$, since whatever set of $n = 6$ operators arise from integrating out the heavy physics can be related to $O_{\text{eff}}$ and $O$, by using the equations of motion. The four scenarios and the corresponding expectations for $= $ are as follows.

(i) $C_{\text{eff}} ( ) = 0, C_{\text{eff}} ( ) = 0$. An expected upper bound on $= $ is given by Fig. 2.

(ii) $C_{\text{eff}} ( ) = 0, C_{\text{eff}} ( ) = 0, C_{\text{eff}} ( ) = 0$. An expected upper bound on $= $ is given by Figs. 5 and 6.

(iii) $C_{\text{eff}} ( ) = 0$ and $C_{\text{eff}} ( ) = 0$. If $C_{\text{eff}} ( )$, then one would expect the maximum possible deviation $= 0$ to be by some combination of curves in Figs. 2, 5 for a specific Higgs mass dependence given in Figs. 6. A conservative estimate is to take the minimum of the curves in Figs. 2 and 5, assuming $m_h$ is not too different from $v$.

(iv) $C_{\text{eff}} ( ) = 0 = C_{\text{eff}} ( )$, leading to no deviation.

We observe that, in all but scenario (iv), an order one shift in the $h ! ^+$ rate is possible when the scale of NP is TeV.

The LHC can look for a deviation from the SM rate of up to 10% or more in $(h ! ^+ )$. Any such deviation would not invalidate the Yukawa mechanism but would be consistent with NP at TeV scales in addition to
the SM Higgs. Thus, it is necessary to disentangle TeV scale effects before drawing any conclusions on the Higgs mechanism for fermion mass generation. The naturalness considerations discussed above imply that a 10% or larger deviation for the decay rate from the SM prediction would be associated with a NP mass scale \( < 10 \text{ TeV} \).

It is also interesting to examine these conclusions in the minimal lepton flavor violation (M LFV) [33, 34, 35, 36, 37, 38, 53] approach, wherein the flavor structure of higher-dimension operators is determined by appropriate insertions of the lepton Yukawa matrix, \( Y \). In the simplest case, the flavor structure of \( O_{\text{eff}} \) and \( O \), would be aligned with \( Y \), so that after diagonalization, the operator coefficients \( C_{\text{eff}} \) and \( C \), would be proportional to \( y \) for a given generation. In order to saturate the naturalness upper bound on \( = \) in M LFV, large Wilson coefficients \( C_{\text{M LFV}} \) \( \sum_{u} x_{i}^{2} = y^{2} \) are required as seen in Eq. (14). However, even with such a large Wilson coefficient \( C_{\text{M LFV}} y = 0.2 \), which is still perturbative. Thus, the upper bound on naturalness can be easily realized in M LFV.

Operators of the form \( O_{\text{eff}} \) and \( O \) could lead to a flavor-changing effects if the flavor structures of \( O_{\text{eff}} \) and \( O \), are not aligned with \( Y \) after diagonalization. In MLFV, for example, the relationships between the flavor diagonal and off-diagonal contributions of these operators can be fixed with a choice of \( e \) content [37]. The off-diagonal flavor-changing effects due to \( O_{\text{eff}} \) and \( O \), contribute at one loop to the flavor-changing decays

\[ B_{j} \rightarrow \nu_{e}, \]

where \( j = \nu_{e} \). From a straightforward dimensional analysis, we find that the naturalness expectations discussed above imply contributions to the decay branching ratios \( B_{j} \rightarrow \nu_{e} \) at order \( 10^{-6} \) \( (m_{H})^{2} (C_{\text{eff}} v^{2} = 2 \hat{C}) \), so that for \( C_{\text{eff}} v^{2} = 2 \), \( y \) as implied by the tree-level naturalness considerations and for \( m_{H} \), one obtains a contribution to \( B_{j} \rightarrow \nu_{e} \) of order \( 10^{-12} \), a result that is seven orders of magnitude smaller the experimental limit. Thus, naturalness considerations lead to considerably more stringent expectations for the dimension six operators than one would infer from these flavor-changing decays.
