Abstract

In this article, we study the nonperturbative dynamics of QCD, final-state interactions and CP violation. The weak Hamiltonian. The nonperturbative hadronic matrix elements of the operators entering the effective weak Hamiltonian. The B factories (BaBar, Belle, etc) have measured the color-suppressed decays to a charmonia and a K (or $K^*$) meson with relatively large branching fractions [1], for example, $\text{Br}(B^0 \to cK) = (8.72 \pm 0.33) \times 10^{-4}$.

The branching fractions are $\text{Br}(B^0 \to cK) = (5.7 \pm 0.6 \pm 0.9) \times 10^{-4}$, $\text{Br}(B^0 \to (2S)K^0) < 3.9 \times 10^{-4}$, $\text{Br}(B^0 \to (2S)K^0) < 4.8 \times 10^{-5}$, $\text{Br}(B^0 \to cK) = (2.2 \pm 0.7) \times 10^{-4}$ at the 90% C.L. [2].

The decays $B^0 \to J = K; cK; cK$ have been calculated with the QCD-improved factorization approach [3,4], there are infrared divergence in vertex corrections and logarithmic divergence in spectator corrections beyond the leading twist approximation for the S-wave charmonia and in the leading twist approximation for the

---

P-wave charmonia, moreover, the predicted branching fractions are too small to accommodate the experimental data \textsuperscript{5,6,7,8,9,10}. The decay \( B^+ \to J^0 = K \) has also been studied with the QCD-improved factorization approach, the factorization breaks down even at the twist-2 level for transverse hard spectator interactions \textsuperscript{11}.

In Refs.\textsuperscript{12,13,14}, the soft nonfactorizable contributions in the decays \( B^+ \to J^0 = K ; c \to K ) \) are studied with the light-cone QCD sum rules, the predicted small branching fractions cannot accommodate the (relatively large) experimental data.

In Ref.\textsuperscript{15}, the authors study the decays \( B^+ \to J^0 = K ) \) with the perturbative QCD approach based on \( k_T \) factorization theorem, and the branching fractions \( Br(B^+ \to K) \) and \( Br(B^+ \to K^0) \) are too small to take into account the experimental data \textsuperscript{2}.

Final-state interactions play an important role in the hadronic \( B \)-decays, the color-suppressed neutral modes such as \( B^0 \to D^0 \to K \) are enhanced substantially by the long-distance rescattering effects \textsuperscript{16}. In Refs.\textsuperscript{17,18}, the authors study the rescattering effects of the intermediate charmed mesons for the decays \( B^+ \to h_c K \) and observe the final-state interactions can lead to larger branching fractions to account the experimental data. The factorizable amplitude in the decay \( B^0 \to K \) is too small to accommodate the experimental data \textsuperscript{2}, so it is interesting to study the effects of the final-state interactions.

The article is arranged as: in Section 2, we study the final-state rescattering effects in the decay \( B^0 \to K \); in Section 3, the numerical result and discussion; and Section 4 is reserved for conclusion.

2 Final-state rescattering effects in the decay \( B^0 \to K \)

The effective weak Hamiltonian for the decay modes \( B \to K \) can be written as (for detailed discussion of the effective weak Hamiltonian, one can consult Ref.\textsuperscript{13})

\[
H_w = \frac{G_F}{2} \sum_{i=3}^{8} V_{cb} V_{cd} \left[ C_1(\sqrt{\Delta}) O_1(\sqrt{\Delta}) + C_2(\sqrt{\Delta}) O_2(\sqrt{\Delta}) \right] V_{tb} V_{ts} \chi_i^{\frac{2}{3}} \frac{\chi_i^{\frac{2}{3}}}{\chi_i^{\frac{2}{3}}} ; (1)
\]
where \( V_{ij} \)'s are the CKM matrix elements, \( C_i \)'s are the Wilson coefficients calculated at the renormalization scale \( O(m_b) \) and the relevant operators \( O_i \) are given by

\[
O_1 = \langle s \ b \rangle_{\nu A} \langle c \ c \rangle_{\nu A}; \\
O_2 = \langle s \ b \rangle_{\nu A} \langle c \ c \rangle_{\nu A}; \\
O_{3(5)} = \langle s \ b \rangle_{\nu A} \langle q \ q \rangle_{\nu A (V+A)}; \\
O_{4(6)} = \langle s \ b \rangle_{\nu A} \langle q \ q \rangle_{\nu A (V+A)}; \\
O_{5(9)} = \frac{3}{2} \langle s \ b \rangle_{\nu A} \langle q \ q \rangle_{\nu A (V+A)}; \\
O_{6(10)} = \frac{3}{2} \langle s \ b \rangle_{\nu A} \langle q \ q \rangle_{\nu A (V+A)}; \\
\]

(2)

and \( i \) are color indexes. We can reorganize the color-mismatched quark dots into color singlet states by Fierz transformation (for example, \( O_2 = \frac{1}{2} O_1 + 2 \phi_1, \phi_1 = (\overline{s} b)_{\nu A} (\overline{c} c)_{\nu A} \), \( a \)'s are the Gell-Mann matrices), and obtain the factorizable amplitude,

\[
h_c(p_3) K(p_4) H_w B(P) i = \frac{G_F}{2} \sqrt{2} V_{cd} V_{us} (C_1 + \frac{C_2}{3}) V_{ub} V_{us} (C_3 C_5 + \frac{C_4 C_6}{3}) \\
h_c(p_3) F (1 \ s) \phi (p_4) F (1 \ s) b B(P) i = \frac{G_F}{2} \sqrt{2} V_{cd} V_{us} (C_1 + \frac{C_2}{3}) V_{ub} V_{us} (C_3 C_5 + \frac{C_4 C_6}{3}) \\
2P_q q M K A_0(p_3); \\
\]

(3)

where we have used the standard definitions for the weak form-factors (we write down all form-factors to be used in this article) \([20,21]\),

\[
h_D (p) F (1 \ s) b B (P) i = (p + P) F_1(q^2) \frac{M_b^2}{q^2} \frac{M_b^2}{q^2} F_0(q^2); \\
h_W (p) F (1 \ s) b B (P) i = i p \ p \ \frac{2V(q^2)}{M_b + M_V} \frac{2M_V q}{q^2} q A_0(q^2) \\
\frac{q}{q^2} q (M_b + M_V) A_1(q^2) + \\
(P + P) \ \frac{M_b^2}{q^2} \frac{M_V^2}{q^2} q \ \frac{A_2(q^2)}{M_b + M_V}; \\
\]

(4)

the \( q \) is the polarization vector of the vector meson and \( q = P \ p \). In this article, we use the value of the B ! K form factor \( A_0(q^2) \) from the light-cone QCD sum rules \([22]\),

\[
A_0(q^2) = \frac{1.364}{1 - q^2/M_b^2} + \frac{0.990}{1 - q^2/36.78}; \\
\]

(5)
The factorizable amplitude (see Eq. (3)) at the tree level is too small to accommodate the experimental data.

The decays $B^0 \rightarrow D D_s, DD_s, D_s D_s, D_s D_s, D_s D_s$ are color enhanced due to the large Wilson coefficient $C_2$.

\[ h_{D_s}(q)D(p)D_s(B)(P)i = P - 2G_F V_{ub}V_{cs}(C_2 + \frac{C_1}{3})P f_{D_s}M_D A_0(q^2); \]

\[ h_{D_s}(q)D(p)D_s(B)(P)i = P - 2G_F V_{ub}V_{cs}(C_2 + \frac{C_1}{3})P f_{D_s}M_D A_0(q^2); \]

we write down only the amplitudes appear in the final expressions. In the heavy quark limit, the weak form factors $A_0(q^2)$ and $F_1(q^2)$ can be related to the universal Isgur-Wise form factor \((!)[23]\).

\[ F_1(q^2) = \frac{M_B^2 + M_D^2}{2M_B M_D} \frac{M_B^2 + M_D^2}{2M_B M_D} \frac{q^2}{q^2}; \]

\[ A_0(q^2) = \frac{M_B^2 + M_D^2}{2M_B M_D} \frac{M_B^2 + M_D^2}{2M_B M_D} \frac{q^2}{q^2}; \]

where \((!)=\frac{2}{3}\), which is compatible with the experimental data for the semileptonic decays $B^0 \rightarrow D (D_J) [24]$.

The decay $B^0 \rightarrow \pi^0 K^-$ can also take place through the decay cascades $B^0 \rightarrow D D_s, D D_s, D_s D_s, D_s D_s, D_s D_s, D_s D_s$; $K^-$, the rescattering amplitudes of $D D_s, D D_s, D_s D_s, D_s D_s, D_s D_s$; $\pi^0 K^-$ may play an important role.

The final-state interactions can be described by the following effective lagrangians,

\[ L_{D D} = \bar{q}_{cD} D c \bar{D} \hat{D} \hat{D} \frac{1}{2} + \bar{q}_{cD} \bar{D} \hat{D} \bar{D} \hat{D} \frac{1}{2} \]

\[ L_{D D} = \bar{q}_{cD} \bar{D} \hat{D} \bar{D} \hat{D} \frac{1}{2} + \bar{q}_{cD} \bar{D} \hat{D} \bar{D} \hat{D} \frac{1}{2} \]

\[ L_{D D} = \bar{D} \hat{D} \bar{D} \hat{D} \frac{1}{2} + \bar{D} \hat{D} \bar{D} \hat{D} \frac{1}{2} \]

\[ L_{D D} = \bar{D} \hat{D} \bar{D} \hat{D} \frac{1}{2} + \bar{D} \hat{D} \bar{D} \hat{D} \frac{1}{2} \]

where the indexes $i; j$ stand for the flavors of the light quarks, $D^{(1)}=D^{(0)}, D^{(1)}$, $D_s^{(1)}, V$ is the $3 \times 3$ matrix for the nonet vector mesons,

\[ \begin{pmatrix}
0 \\
\frac{1}{2} + \frac{1}{2} \\
\frac{1}{2} + \frac{1}{2}
\end{pmatrix}
\]

\[ V = \begin{pmatrix}
K & 0 & C \\
0 & K & A \\
C & A & K
\end{pmatrix}
\]

The lagrangians $L_{D D V}, L_{D D V}$ and $L_{D D V}$ are taken from Ref. [16], and the $L_{DD D}$ and $L_{DD D}$ are constructed from the heavy quark theory in this article. In the heavy quark limit, the strong coupling constants $f_{D D V}, f_{D D V}, g_{D D V}$ and $g_{D D V}$ can be
related to the basic parameters and in the heavy quark effective Lagrangian (one can consult Ref. [25] for the heavy quark effective lagrangian and relevant parameters, we neglect them for simplicity),

$$f_{D D V} = f_{D D V} = \frac{g_v}{2};$$
$$g_{D D V} = g_{D D V} = \frac{g_v}{2};$$

(14)

where $g_v = 5.8$ from the vector meson dominance theory [26]. The strong coupling constants $g_{c D D}$ and $g_{c D D}$ are estimated with the universal Isgur-Wise form-factor at zero recoil (1) and the assumption of dominance of the intermediate $c$ meson for the pseudoscalar heavy quark current $\overline{c} s C$,

$$g_{c D D} = \frac{2m_c}{f_c} \frac{M}{f_c};$$
$$g_{c D D} = \frac{g_{c D D}}{M_D}.$$  

(15)

The rescattering effects can be taken into account by twelve Feynman diagrams, see Fig.1. We calculate the absorptive parts (or imaginary parts) of the rescattering
amplitudes \( \text{Abs}(i) \) by the Cutkosky rule, \( \text{Abs}(i) = \text{Abs}(i) \frac{Z}{V_{cb} V_{cs}} (C_2 + \frac{C_1}{3}) \),

\[
\begin{align*}
\text{Abs}(a) &= \frac{p_1}{8M_B} \frac{Z}{Z} \quad d \quad f_{D_s M_D} g_{\gamma D_D} g_{D D D} A_0(p_2^2) \frac{F^2(M_D; i t)}{t M^2_D} \\
\text{Abs}(b) &= \frac{p_1}{8M_B} \frac{Z}{Z} \quad d \quad f_{D_s M_D} g_{\gamma D_D} g_{D D V} F_1(p_2^2) \frac{F^2(M_{D_s}; i t)}{t M^2_{D_s}} \\
\text{Abs}(c) &= \frac{p_1}{4M_B} \frac{Z}{Z} \quad d \quad f_{D_s M_D} g_{\gamma D_D} g_{D D D} f_{D D V} A_0(p_2^2) \frac{F^2(M_D; i t)}{t M^2_D} \\
\text{Abs}(d) &= \frac{p_1}{4M_B} \frac{Z}{Z} \quad d \quad f_{D_s M_D} g_{\gamma D_D} g_{D D D} f_{D D V} F_1(p_2^2) \frac{F^2(M_{D_s}; i t)}{t M^2_{D_s}} \\
\text{Abs}(e) &= \frac{p_1}{8M_B} \frac{Z}{Z} \quad d \quad f_{D_s M_D} g_{\gamma D_D} g_{D D D} F_1(p_2^2) \frac{F^2(M_D; i t)}{t M^2_D} \\
\text{Abs}(f) &= \frac{p_1}{8M_B} \frac{Z}{Z} \quad d \quad f_{D_s M_D} g_{\gamma D_D} g_{D D D} A_0(p_2^2) \frac{F^2(M_{D_s}; i t)}{t M^2_{D_s}} \\
\text{Abs}(g) &= \text{Abs}(h) \quad (\text{in SU(3) limit}) \\
\text{Abs}(i) &= \text{Abs}(j) \quad (\text{in SU(3) limit}) \\
\text{Abs}(k) &= \text{Abs}(l) \quad (\text{in SU(3) limit}) \quad (16)
\end{align*}
\]

where \( p_1 \) is the 3-momentum of the on-shell intermediate mesons \( D_{i} D_{i} \) \( D_{s} D_{s} \) in the rest frame of the meson, for example, in the process \( B^0 \rightarrow D_{i} (p_1) \bar{D}_{s} (p_2) \) \( c(p_3) \bar{K} (p_4), t = q^2, q = p_1 - p_3, p_3 = p_4 \), \( p_2 \) \( p_i \) is the polarization vector of the vector meson \( i \). The \( c \) -channel effects of the \( t \)-channel exchanged mesons \( D_{i} D_{i} \) \( D_{s} D_{s} \) and \( D_{s} D_{s} \) are taken into account by introducing a monopole form-factor \( F(t) \),

\[
F(M_i; t) = \frac{M^2_i}{t} \quad (17)
\]

and the cut-off \( Q_{CD} \) are parameterized as

\[
Q_{CD} = M_{i} + Q_{CD} \quad (18)
\]
where \( g_s \) is a free parameter and \( \phi_{CD} = 0.225 \text{ GeV} \). In fact, the \( g_s F(M; t) \) are the momentum dependent strong coupling constants, we can vary the parameter to change the effective strong couplings, here we use the notation \( g_s \) to denote all the strong coupling constants.

The dispersive parts (or real parts) of the rescattering amplitudes can be obtained via the dispersion relation,

\[
D \mathrm{is}(i)(M_B^2) = -\frac{1}{\pi} \int_{s_{th}}^{\infty} \frac{Z_1 A \mathrm{bs}(s^0)}{s^0 - M_B^2} \mathrm{d}s^0;
\]

where the thresholds \( s_{th} \) are given by \( s_{th} = (M_D + M_{D_s})^2, (M_D + M_{D_s})^2, (M_D + M_{D_s})^2 \) for any specific diagram. There are large uncertainties due to the cut-off procedure, even one assumes that the integrals are dominated by the region close to the pole \( M_B^2 \) [17,18]. In this article, we assume the dominating contributions of the rescattering amplitudes come from the absorptive parts, which originate from the on-shell intermediate states in the decay cascades, the dispersive parts of the amplitudes are of minor importance and can be taken into account by introducing a phenomenological parameter \( \lambda \), \( D \mathrm{is}(i) = A \mathrm{bs}(i) \), 30%.

3 Numerical result and discussions

The CKM matrix elements are taken as \( V_{ub} = 0.07296 \pm 0.00024, V_{cb} = (41.5 \pm 0.6) \times 10^{-3} \) and \( V_{td} = 0.999101^{+0.00034}_{-0.00004} \) and \( V_{ts} = (40.6 \pm 2.7) \times 10^{-3} \) [1,27]. We take the next-to-leading order W boson coefficients calculated in the naive dimensional regularization scheme for \( = m_B(\mu_B) = 4\times10^6 \text{ GeV} \), and \( = 225 \text{ GeV} \), \( C_1 = 0.085, C_2 = 1.082, C_3 = 0.014, C_4 = 0.035, C_5 = 0.009 \), and \( C_6 = 0.041 \) [19], here we have neglected the W boson coefficients \( C_7, C_8, C_9, C_{10} \) in numerical calculation due to their small values. The masses of the mesons are taken as \( M_B = 5.279 \text{ GeV} \), \( M_K = 0.892 \text{ GeV} \), \( M_{D} = 1.87 \text{ GeV} \), \( M_{D_s} = 1.97 \text{ GeV} \), \( M_{D_s} = 2.11 \text{ GeV} \), and \( M_{D_s} = 2.986 \text{ GeV} \) [2].

The values of the decay constants \( f_D, f_{D_s}, f_D \) and \( f_{D_s} \) vary in a large range from different approaches, for example, the potential model, QCD sum rules and lattice QCD, etc [30,31,32]. For the \( f_D \), we take the experimental data from the CLEO Collaboration, \( f_D = 222.3 \pm 16.7^{+2.3}_{-3.8} \text{ GeV} \) [33,34]. The value \( f_{D_s} = 0.274 \pm 0.013 \text{ GeV} \) from the CLEO Collaboration shows the SU(3) breaking effect is rather large [35], \( f_{D_s} \) is 123, while most of theoretical calculations indicate \( f_{D_s} \) 111, we take the value \( f_{D_s} = f_D = 0.22 \pm 0.02 \text{ GeV} \), and \( f_{D_s} = f_{D_s} = 0.24 \pm 0.02 \text{ GeV} \).

The decay constant \( f_D \) can be estimated with the QCD sum rules [36] or phenomenological potential models, the values from those approaches are compatible with each other, we can take the value \( f_D = 0.35 \pm 0.02 \text{ GeV} \) [37,38,39].

The basic parameters in the heavy quark effective Lagrangian are estimated with the vector meson dominance theory [28,29], \( = 0.56 \text{ GeV} \) and
Figure 1: The Feynman diagrams for the final-state interactions.
The corresponding values of the strong coupling constants are

\[
\begin{align*}
    f_{D_DV} &= 2.30 \text{ GeV}^{-1} ; \\
    f_{D_DV} &= 4.51 ; \\
    g_{D_DV} &= 3.69 ; \\
    g_{D_DV} &= 3.69 ;
\end{align*}
\]

while the values from the light-cone QCD sum rules are much smaller \[40,41\]. In this article, the strong coupling constants \(g_{cD_D}\) and \(g_{cD_D}\) are estimated with the universal Isgur-Wise form-factor at zero recoil \(1\) and the assumption of dominance of the intermediate \(c\) meson for the pseudoscalar heavy quark current \(\bar{Q}c\). We take the results from the vector meson dominance theory for consistency. However, we may overestimate the final-state rescattering effects due to the larger strong coupling constants, and have to compensate them with suitable

The parameters \(\alpha = 0.3, = 1.4, 1.8\). The contributions from the rescattering effects are somewhat sensitive to the parameter \(\alpha\) in the form-factors, the \(\alpha\) is of the order of the mass of radial excitations of the charm mesons \[17,18\].

Finally we obtain the numerical results for the branching fractions,

\[
\begin{align*}
    \text{Br}(B^0 \to K) &= (3.25 \pm 0.99) \times 10^{-4} \ (\text{Tree amplitude}); \\
    \text{Br}(B^0 \to K) &= (3.90 \pm 0.31) \times 10^{-4} \ (\text{Tree+Abs amplitude}); \\
    \text{Br}(B^0 \to K) &= (4.83 \pm 0.94) \times 10^{-4} \ (\text{Tree+Abs+Dist amplitude}); \\
    \text{Br}(B^0 \to K) &= (5.7 \pm 0.6 \pm 0.9) \times 10^{-4} \ (\text{Experimental data});
\end{align*}
\]

4 Conclusion

In this article, we study the final-state rescattering effects in the decay \(B^0 \to K\), the numerical results indicate the corrections are comparable with the contribution from the naive factorizable amplitude, and the total amplitudes can accommodate the experimental data.
