\(^4\)Dated: July 20, 2013

We compute the tree-level connected four-point function of the primordial curvature perturbation for a fairly general minimally coupled single field in arbitrary model, where the in atom's Lagrangian is a general function of the scalar field and its first derivatives. This model includes K-in-action and DBI-in-action as particular cases. We show that, at the leading order in the slow-roll expansion and in the small sound speed limit, there are two important tree-level diagrams for the trispectrum. One is a diagram where a scalar mode is exchanged and the other is a diagram where the interaction occurs at a point, i.e., a contact interaction diagram. The scalar exchange contribution is comparable to the contact interaction contribution. For the DBI-in action model, in the so-called equilateral configuration, the scalar exchange trispectrum is maximized when the angles between the four momentum vectors are equal and in this case the amplitude of the trispectrum from the scalar exchange is one order of magnitude higher than the contact interaction trispectrum.

I. INTRODUCTION

Recent observations of the cosmic microwave background (CMB) anisotropies suggest that a non-Gaussian component will contribute to a huge advance in our understanding of the very early universe. For example, the simplest and most popular in arbitrary model based on a single field with a canonical kinetic term satisfying slow-roll conditions and standard initial conditions predicts that the level of primordial non-Gaussianity is actually unobservable on all scales, even with future CMB experiments like the Planck satellite. However, there are some hints of non-Gaussianity in the CMB anisotropies. These are one (or so) standard deviation hints but they motivate tremendous efforts from the theoretical cosmology community to create in arbitrary models that can produce large levels of non-Gaussianity both seen in the bispectrum and in the trispectrum. In the literature, there are a myriad of models, including large bispectrum and also large trispectrum of the primordial curvature perturbation. In particular the DBI-in-action model, which is constructed within string theory, is such an example. For current and stringent observational constraints and consequences of DBI-in-action see [55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65].

We will focus our attention on the trispectrum of the primordial curvature perturbation. The current observational bound \[ {\mathcal{L}}_{\text{N}} < 10^8 \] on the trispectrum is rather weak, where \[ N \] parameterizes the size of the trispectrum, but in the near future with the Planck satellite it will be possible to probe \[ N \approx 500 \]. We should note that these bounds depend on the shape of the trispectrum and the values quoted here can be applied only for local models of non-Gaussianity. Thus it is important to calculate the exact form of the trispectrum in the DBI-in-action model and construct an estimator to measure the trispectrum of the CMB anisotropies.
In [68], Seery et al. calculated the contact interaction trispectrum for slow-roll multiple eikai in action but with standard kinetic terms. They showed that at horizon crossing the contact interaction trispectrum is too small to be observed. They found that, \( r = C_1 \), where \( r \) is the tensor to scalar ratio, that is currently constrained to the range \( r < 0.22 \) at 95% confidence level [4]. Recently, Seery et al. [69] computed the graviton exchange trispectrum and they showed that the above conclusion does not change, i.e., the total non-linearity parameter \( \eta_{NL} \) coming from both the contact interaction and the graviton exchange trispectrum is still unobservably small and of order \( r \). Also recently, Gao and Hu [43] computed the leading order trispectrum from entropy perturbations in multi eikai DBI-in action model.

In [23] (see also [33]), the authors computed the trispectrum at leading order in slow-roll and in the small sound speed limit for a fairly general in actionary model, where the in atom's Lagrangian is a general function of the scalar eikai and its rst derivatives. They only calculated the contact interaction trispectrum and they argue that for certain models (DBI-in action inclusive) the trispectrum can reach values in the observable range of the Planck satellite.

In the present work, we will calculate the scalar exchange trispectrum for the same model. We will show that the scalar trispectrum is of the same importance as the contact interaction trispectrum. This complements the work of [23] (see also [33]) and gives the nal answer that should be constrained when comparing the trispectrum for models with large non-Gaussianity with observations.

The rest of this paper is organized as follows. In the next section, we will introduce the model and some basic notations. In section III, we will consider non-linear perturbations in the action up to quartic order. In subsection IIIA, we will present a simple argument to prove that the amplitude of the scalar exchange trispectrum is of the same order of magnitude as the contact interaction trispectrum. In subsection IIIB, we will calculate the trispectrum of the primordial curvature perturbation at leading order in slow-roll and in the small sound speed limit when only contact interactions are taken into account. In subsection IIIC, we will calculate the scalar exchange trispectrum. At the end of this subsection, we present for the rst time the complete trispectrum at leading order in the previously mentioned approximations. Section IV is devoted to the study of the shape of the trispectrum in the so-called equilateral configuration for the DBI-in action model. We will also compute the non-linearity parameter \( \eta_{NL} \) for different models. The conclusions of this work are described in section V.

II. THE MODEL

In this section, we will introduce the in actionary model under study. We shall present the background equations of motion and define the slow-variation parameters. At the end of the section, we show the results for the primordial power spectrum of the curvature perturbation and the spectral index [70].

We will consider a fairly general class of models described by the following action

\[
S = \frac{1}{2} \int d^4x \sqrt{-g} \left( \frac{M_P^2}{4} R + 2P(X) \right);
\]

where \( g \) is the metric tensor. We label the in atom's Lagrangian by \( P \) and we assume that it is a well-behaved function of two variables, the in atom eikai and \( X \). Throughout this work, we use a system of units where the Planck constant \( \hbar \) is the speed of light \( c \), and the reduced Planck mass \( M_P \) is set to unity. This general Lagrangian includes as particular cases the DBI-in action model [13, 54] and the K-in action model [71]. In the DBI-in action model, \( P(X) \) is given by

\[
P(X) = f(V(X)),
\]

where \( f(\cdot) \) and \( V(\cdot) \) are functions of the scalar eikai determined by string theory configurations. At the background level, we assume that our Universe is well described by a flat, homogeneous and isotropic Friedmann-Robertson-Walker universe given by the line element

\[
ds^2 = dt^2 + a(t)^2 \sum dx^i dx^j;
\]

where \( a(t) \) is the scale factor. The Friedmann equation and the continuity equation read

\[
3H^2 = \frac{\rho}{3} = \dot{a} = aE;
\]

\[
E = 3H(E + P);
\]

where \( \dot{ } \) denotes derivative with respect to cosmic time \( \frac{d}{dt} \), the Hubble rate is \( H = \frac{\dot{a}}{a} \), \( E \) is the energy of the in atom and it is given by

\[
E = 2X P_X P;
\]
where $P_{\kappa}$ denotes the derivative of $P$ with respect to $X$. It was shown in [70] (see also [74]) that for this model the speed of propagation of scalar perturbations (\"speed of sound\") is $c_s$ given by

$$
c_{s}^{2} = \frac{P_{\kappa}}{E_{\kappa}} = \frac{P_{\kappa}}{P_{\kappa} + 2X P_{\kappa X}};
$$

(7)

We define the slow variation parameters, analogues of the slow-roll parameters, as:

$$
= \frac{H}{a} = \frac{X P_{\kappa}}{H^{2}};
= \frac{H}{a} = \frac{s}{c_{s} H};
$$

(8)

We should note that these slow variation parameters are more general than the usual slow-roll parameters and that the smallness of these parameters does not imply that the field is rolling slowly. We assume that the rate of change of the speed of sound is small (as described by $s$) but $c_s$ is otherwise free to change between zero and one.

The power spectrum of the primordial quantum fluctuation was first derived in [74] and reads

$$
P(k) = \frac{1}{36} \frac{E^{2}}{E + P} = \frac{1}{8} \frac{H^{2}}{c_{s}^{2}};
$$

(9)

where it should be evaluated at the time of horizon crossing $c_s k = a H$. The spectral index is

$$
n = \frac{d \ln P(k)}{d \ln k} = 2, \quad s;
$$

(10)

WMAP observations of the perturbations in the CMB tell us that the previous power spectrum is almost scale invariant therefore in plying that the slow variation parameters should be small at horizon crossing, roughly of order $10^{-5}$.

### III. NON-LINEAR PERTURBATIONS

The main goal of this section is to calculate the total connected trispectrum of the primordial curvature perturbation for the model [1], at leading order in the slow-roll expansion and in the limit of small sound speed. In the next subsection, with very simple arguments, we will estimate the order of magnitude of the trispectrum coming from the scalar exchange and compare it with the result of the trispectrum coming from the contact interaction [25] (see also [30]). In subsection III.B, we review the calculation of the contact interaction trispectrum. Finally, in subsection III.C, we calculate the scalar exchange trispectrum. The total trispectrum will be the sum of these contributions.

Non-linear perturbations of the model [1] have been considered by several authors before. In [14], Gruzinov obtained the bispectrum using the simple method of expanding the action of the field in slow roll and in the small sound speed limit. In [24], the authors perform a detailed analysis of the bispectrum produced in the present model including also next order terms in slow-roll and small sound speed expansion. The trispectrum has also been studied in the literature. In particular, Chen et al. [29] (see also [30]) calculated the trispectrum from the contact interaction.

The Lagrangian density of the field expanded up to fourth order in perturbations (at leading order in slow-roll and in the small sound speed limit) can be found in [29], and it reads

$$
L^{(2)} = \frac{a^{3} P_{\kappa}}{2 c_{s}^{2}} \frac{P_{\kappa}}{2} \left[ \frac{d}{d t} \right]^{2};
$$

(11)

$$
L^{(3)} = P_{\kappa} x - P_{\kappa} x - \frac{a^{3} P_{\kappa} X}{2} P_{\kappa} x - \frac{P_{\kappa} X}{2} a \left[ \frac{d}{d t} \right]^{2};
$$

(12)

$$
L^{(4)} = \frac{a^{3}}{2} \frac{P_{\kappa} X}{4} \frac{4}{P_{\kappa} X} + \frac{1}{P_{\kappa} X} \frac{P_{\kappa} X}{4} \left[ \frac{d}{d t} \right]^{2} - \frac{P_{\kappa} X}{4} \frac{P_{\kappa} X}{4} \left[ \frac{d}{d t} \right]^{2};
$$

(13)

where denotes the field perturbation $(t,x)$. 
In the next subsections, we will use the so-called \"interaction picture form\" [7] to calculate the four-point quantum correlation function. In this form, one needs to know the interaction Hamiltonian. The Hamiltonian density \( H \) can be found using Eqs. (11), (12), (13) and

\[
H = - L \tag{14}
\]

where \( L \) is the Lagrangian density and \( \varphi \) is the momentum density, defined by \( \varphi = \partial L/\partial _{\varphi} \). The third order Hamilton density is \( H^{(3)} = L^{(3)} \) and the fourth order Hamilton density is [23]

\[
H^{(4)} = 1a^{3} + 2a_{\varphi}^{2}\varphi + 3a^{4} ; \tag{15}
\]

where \( \varphi \) is the momentum density, defined by \( \varphi = \partial L/\partial _{\varphi} \). Finally, to obtain the interaction Hamiltonian from the (15), the variables \( \varphi \) and \( \varphi \) should be replaced with their interaction picture counterparts \( \varphi \) and \( \varphi \).

The constants \( i \) are defined as

\[
\begin{align*}
1 & = P_{\varphi} x \times \frac{9}{8} \varphi_{\varphi} - \frac{3}{2} P_{\varphi} x x \times \frac{3}{4} \varphi_{\varphi} + \frac{1}{8} \delta_{\varphi} P^{2}_{\varphi} x x \times \frac{1}{24} P_{\varphi} x ; \\
2 & = \frac{1}{2} P_{\varphi} x \times \frac{3}{2} \varphi_{\varphi} + \frac{1}{4} \frac{3}{2} \varphi_{\varphi} P_{\varphi} x x ; \\
3 & = \frac{1}{2} P_{\varphi} x : . \tag{16}
\end{align*}
\]

For DBI interaction, at leading order in the sound speed, the constants are

\[
\begin{align*}
1 & = \frac{1}{2c_{s}^{2}} ; \\
2 & = \frac{1}{4c_{s}^{2}} ; \\
3 & = \frac{1}{8c_{s}^{2}} ; \tag{17}
\end{align*}
\]

From the second-order action, we can solve for the perturbation and quantize it according to the standard procedures of quantum field theory:

\[
( ; x) = \frac{1}{(2\pi)^{3}} \zeta^{3} k u ( ; k) a(k) + u ( ; k) \bar{a}(k) \bar{a}^{k} ; \tag{18}
\]

where \( u( ; k) = \frac{\delta_{\varphi}}{2k} P_{\varphi} \frac{1}{c_{s}} (1 + \text{ikcs} \rho e) \text{iks} \) is the solution of the quadratic Lagrangian, and \( \text{cosh} \) is the conformal time. The commutation relations are given by

\[
[a(k_{1});a(k_{2})] = [a^{\dagger}(k_{1});a^{\dagger}(k_{2})] = 0 ; \quad [a(k_{1});a^{\dagger}(k_{2})] = (2 \pi)^{3} (3) k_{1} k_{2} ; \tag{19}
\]

A. Estimate of the amplitude of the total trispectrum

In this subsection, we shall present a very simple argument to prove that the trispectrum coming from the contact interaction diagram is of the same order as the trispectrum coming from the scalar exchange diagram. Therefore, the total trispectrum is the sum of these two contributions. For simplicity, we will consider the DBI-interaction case but the conclusion is valid for generic models of the form [1].

Let us start by drawing the tree-level diagram that contributes to the bispectrum. It can be found in Fig. 1, and it is composed of two external lines labeled by \( T^{SE} \) and \( P^{3} I_{1}^{2} \). The third order vertex is given by \( I_{3} \), and it has three scalar propagators \( P^{3} = H^{2} c_{s}^{-1} \), and one third order vertex \( I_{3} \) as depicted in the l.h.s. of Fig. 2. The bispectrum coming from this diagram is then \( B P^{3} I_{3} \).

The third order vertex is given by \( I_{3} \), and it has three scalar propagators \( P^{3} = H^{2} c_{s}^{-1} \), and one third order vertex \( I_{3} \) as depicted in the l.h.s. of Fig. 2. The bispectrum coming from this diagram is then \( B P^{3} I_{3} \).

For the trispectrum, there are two relevant tree-level diagrams, Fig. 3. If we denote the fourth order vertex on the r.h.s. of Fig. 3 by \( I_{4} \), then the diagram on the r.h.s. of Fig. 3 gives a contribution to the trispectrum as \( c_{s} P^{3} I_{4} \). From the fourth order Hamiltonian, the fourth order vertex is estimated as \( I_{4} \), and the diagram on the r.h.s. of Fig. 3 gives \( T^{SE} P^{3} I_{4}^{2} \). The total trispectrum is easily calculated as \( T^{SE} c_{s} P^{3} I_{4}^{2} \), which has the same magnitude as \( T^{C} c_{s} P^{3} I_{4}^{2} \). Therefore, for consistency the total trispectrum is the sum of \( T^{C} c_{s} P^{3} I_{4}^{2} \).
Recently, [69] showed that in the case of the standard kinetic term, i.e. when $P = X = V(\phi) + (\phi)V''(\phi)$ is the potential, the diagram where we have an exchange of a graviton can in fact dominate the contact interaction diagram. In this model, the contribution from the scalar exchange diagram is negligible in comparison with both the contact interaction and the graviton exchange. They showed that the contact interaction trispectrum is $T_C^P = P^3$, the graviton exchange trispectrum is $T_{GE}^P = P^3$ and the scalar exchange trispectrum is $T_{SE}^P = 2P^3$. The third order scalar vertex is $I_3^H$, the fourth order vertex is $I_4^H$. We have checked that in the case of non-standard kinetic terms the graviton exchange diagram gives a contribution to the trispectrum that is suppressed by $\alpha$ with respect to the leading order and we neglect this contribution. This fact can be easily understood if one uses the main result of [69] and one recalls Maldecena's result [4] that the third order vertex of two-scalars-one-graviton is $I_3^H$.

In the next subsections, we will derive the momentum dependence of the trispectrum from the contact interaction and the scalar exchange.

**B. The trispectrum from the contact interaction**

In this subsection, we shall make use of the so-called interaction picture form [73] to calculate the four-point function of the field perturbation at horizon crossing coming from a diagram like the one on the l.h.s. of Fig. 3. The result can also be found in Chen et al. [25] (see also [24]). These results are at leading order in slow-roll and in the limit of small sound speed. For the contact interaction diagram, the four-point function is

\[
\left\langle h (0; k_1) h (0; k_2) h (0; k_3) h (0; k_4) \right\rangle = \int \frac{d^3 k}{(2\pi)^3} \left\langle \delta (k_1 + k_2 + k_3 + k_4) \right\rangle \frac{1}{(2\pi)^4} \left[ \frac{1}{(k_1 + k_2 + k_3 + k_4)^2} \right]
\]

where $H_4^1$ is the fourth order interaction Hamiltonian given by $H_4^1 = \frac{R}{d^3 x} R^4$. It can be found from Eq. (15) and reads

\[
H_4^1 = \frac{Z}{d^3 x} \left[ \frac{h}{(k_1 + k_2 + k_3 + k_4)^2} + \frac{\partial_1}{(k_1 + k_2 + k_3 + k_4)^2} + \frac{\partial_2}{(k_1 + k_2 + k_3 + k_4)^4} \right];
\]

where $\partial^i$ denotes derivative with respect to conformal time $\tau$. 

**FIG. 1: B ispectrum diagram**

**FIG. 2: On the left: the third order vertex. On the right: the fourth order vertex**
For a generic K-in action model, we obtain

\[
\begin{align*}
&\frac{1}{1152} N^8 c_5 \quad \frac{1}{P^4} \quad \frac{1}{k_1} \quad \frac{1}{k_3} \quad \frac{1}{k_5} \\
&+ \frac{4}{2} N^8 c_5 \quad \frac{k_1^2 k_2^2}{P^4} \quad \frac{k_1^2}{k_3} \quad \frac{k_1^2}{k_5} \\
&\quad \text{permutations}
\end{align*}
\]

where the total moment \( K \) is defined by \( K = k_1 + k_2 + k_3 + k_4 \), the constant \( N \) is defined by \( N = H = \frac{P}{2F} \) and \( c_5 \) and \( \text{permutations} \) denote the other twenty three terms that result from the permutations of \( k_1, k_2, k_3, k_4 \) in the preceding term. The three dimensional Dirac delta function of \( K \) ensures momentum conservation and implies that the four momenta vectors \( k_i \), where \( i = 1, \ldots, 4 \), form a quadrilateral.

For DIBI action, in the small sound speed limit, the terms proportional to \( 2 \) and \( 3 \) are sub-leading with respect to the term proportional to \( 1 \). For K-in action models, this is not necessarily the case and this fact can be used to distinguish some K-in action models from DIBI action [22].

To obtain the four-point correlation function of the curvature perturbation at some time after horizon crossing we can use the linear relation \( \langle H \rangle = \langle H \rangle \) because the higher order terms in this relation only generate sub-leading corrections to this result and therefore we ignore them. Finally, we obtain

\[
\begin{align*}
&h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ j \ f^{E} = \frac{H^4}{2} h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ j \ f^{E}.
\end{align*}
\]

C. The trispectrum from the scalar exchange interaction

Within the interaction picture form of Vains, to calculate the four-point function resulting from a correlation established via the exchange of a scalar mode as depicted in the right hand side of Fig. 3 one needs to evaluate the following time integrals

\[
\begin{align*}
&h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ j \ f^{E} \\
&\quad = \int_1 h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ H^{(2)}(1) \ H^{(2)}(2) \ j \ f^{E}.
\end{align*}
\]

where \( H^{(2)}(1) \) is the third order interaction Hamiltonian given by \( H^{(2)} = R^3 x H^{(2)} \) and \( R^3 x L^{(2)} \). We will use

\[
\begin{align*}
&h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ j \ f^{E} \\
&\quad = \int_1 h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ H^{(3)}(1) \ H^{(3)}(2) \ j \ f^{E}.
\end{align*}
\]

\[
\begin{align*}
&h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ j \ f^{E} \\
&\quad = \int_1 h \ j \ (0;k_1) \ (0;k_2) \ (0;k_3) \ (0;k_4) \ H^{(3)}(1) \ H^{(3)}(2) \ j \ f^{E}.
\end{align*}
\]
where the constants $A$ and $B$ are defined as

$$A = \frac{-1}{2} P_{\mathbf{k} \times} x + \frac{1}{3} - \frac{2}{3} P_{\mathbf{k} \times x} ; \quad B = \frac{-1}{2} P_{\mathbf{k} \times} x :$$

(26)

For DIB interaction they are given by

$$A = \frac{1}{2 - c_0^2} ; \quad B = \frac{1}{2 - c_0^2} :$$

(27)

The calculation of the integral in [24] is rather long but relatively straightforward (however see [24]). The total four-point function of the field perturbations is

$$h \ j (0; k_1) \ (0; k_2) \ (0; k_3) \ (0; k_4) j \ F_c = (2 \ j)^3 (k_1 k_2 k_3 k_4) \frac{2N^4}{(k_1 k_2 k_3 k_4)^2}$$

$$9A^2 \ F_1 (k_1; k_2; k_3; k_4; k_{12}) \ F_1 (k_1; k_2; k_3; k_4; k_{12})$$

$$+ AB \ 3(k_3 \ k_4) \ F_3 (k_1; k_2; k_3; k_4; k_{12}) \ F_3 (k_1; k_2; k_3; k_4; k_{12})$$

$$+ 6(k_{12}) \ k \ F_3 (k_1; k_2; k_3; k_4; k_{12}) \ F_3 (k_1; k_2; k_3; k_4; k_{12})$$

$$+ 3(k_1 \ k_2 \ k_3) \ F_4 (k_1; k_2; k_3; k_4; k_{12}) \ F_4 (k_1; k_2; k_3; k_4; k_{12})$$

$$+ 6(k_{12} \ k_4) \ F_4 (k_1; k_2; k_3; k_4; k_{12}) \ F_4 (k_1; k_2; k_3; k_4; k_{12})$$

$$B^2 \ (k_1 \ k_2 \ k_3) \ F_2 (k_1; k_2; k_3; k_4; k_{12}) \ F_2 (k_1; k_2; k_3; k_4; k_{12})$$

$$+ 2(k_1 \ k_2 \ k_3) \ F_2 (k_1; k_2; k_3; k_4; k_{12}) \ F_2 (k_1; k_2; k_3; k_4; k_{12})$$

$$+ 2(k_1 \ k_2 \ k_3) \ F_2 (k_1; k_2; k_3; k_4; k_{12}) \ F_2 (k_1; k_2; k_3; k_4; k_{12})$$

$$+ 23 \ \text{permutations of} \ k_1; k_2; k_3; k_4 \ ;$$

(28)

where as before $K = k_1 + k_2 + k_3 + k_4, N = H = \sum P_{\mathbf{k} \times} k_i$ and $k_{12} = j = k_1 + k_2. \ \text{Similarly, we define} \ k_{ab} = j = k_a + k_b \ \text{where} \ k_a \ \text{and} \ k_b \ \text{represent any of the four moment vectors} \ k_1, k_2, k_3 \ \text{and} \ k_4. \ \text{Mom} \ \text{moment conservation in planes} \ k_{12} = k_{13} = k_{23} \ \text{and} \ k_{14} = k_{23}.$

Because there are only four different types of double time integrals over the mode functions, we define four $F$ functions (with $i = 1; \ldots; 4$). Their explicit expressions are

$$Z_{0}^{0} \ \text{as the sum of the last three arguments of the} \ \text{functions} \ A = k_4 + k_5 + k_6 \ \text{C} \ \text{is defined}$$

$$F_1 (k_1; k_2; k_3; k_4; k_5; k_6) = \frac{1}{N} \ \sum_{j=1}^{6} \ \sum_{i=1}^{1} \ 1 + \frac{A}{C} + \frac{A^2}{C^2}$$

(29)
by the sum of all the arguments as \( C = k_1 + k_2 + k_3 + k_4 + k_5 + k_6 \). The remaining functions are

\[
F_2(k_1; k_2; t; k_4; k_5; k_6) = \frac{Z_0}{Z} \left( \frac{1}{H} \right)^2 \left( \frac{k_1 k_4 f}{k_2 k_3 k_5 k_6} A \right)^2 \frac{1}{1 + \frac{k_5 + k_6}{A} + 2 \frac{k_5 k_6}{A^2}} + \frac{1}{C} \left( \frac{k_2 + k_3 + k_5 + k_6}{A} + \frac{1}{A} \right) \left( \frac{(k_2 + k_3)(k_5 + k_6) + 2k_5k_6}{A^2} \right)
\]

The sum of all the arguments as \( C = k_1 + k_2 + k_3 + k_4 + k_5 + k_6 \). The remaining functions are

\[
F_3(k_1; k_2; k_3; t; k_4; k_5; k_6) = \frac{Z_0}{Z} \left( \frac{1}{H} \right)^2 \left( \frac{k_1 k_2 k_3 k_4 f}{k_5 k_6} A \right)^2 \frac{1}{1 + \frac{k_5 + k_6}{A} + 2 \frac{k_5 k_6}{A^2}} + \frac{3}{C} \left( \frac{k_2 + k_3}{A} + \frac{2}{C} \right) \left( \frac{k_5 + k_6 + 2k_5k_6}{A} + \frac{12k_5k_6}{C^2} \right)
\]

\[
F_4(k_1; k_2; k_3; t; k_4; k_5; k_6) = \frac{Z_0}{Z} \left( \frac{1}{H} \right)^2 \left( \frac{k_1 k_2 k_3 k_4 f}{k_5 k_6} A \right)^2 \frac{1}{1 + \frac{k_5 + k_6}{A} + 2 \frac{k_5 k_6}{A^2}} + \frac{3}{C} \left( \frac{A}{C} \right) \left( \frac{k_2 + k_3}{C} + \frac{2}{C^2} \right) \left( \frac{A k_5 + k_6 + 12k_5k_6}{A} + \frac{12k_5k_6}{C^2} \right)
\]

where the function \( U(ik) \) is a modified mode function given by

\[
U(ik) = \frac{N 1}{k f} (1 + i k c) e^{ikc} ;
\]

If the sign of the argument \( k \) is positive then \( U \) is equal to the mode function, if the sign is negative then \( U \) equals the complex conjugate of the mode function.

The study of the momentum dependence of the trispectrum will be the subject of the next section, but here we would like to make a remark. In the configuration where all the momentum vectors have equal magnitude, it is easy to see that the variable \( C \) defined previously and that appears in some \( F_i \) functions in \( \text{[2]} \) become zero. Because \( C \) appears in the denominator of some fractions in the definitions of \( F_i \) one might naively think that the trispectrum diverges for these configurations. This is not the case. In Appendix \( \text{[A]} \), we show that if one includes all the permutations of these terms the apparent divergences do not appear anymore and as expected the trispectrum is finite for these configurations.

As in the previous subsection, the four-point function of the curvature perturbation is related with the four-point function of the \( \xi \) perturbation as

\[
h_j(0; k_1) (0; k_2) (0; k_3) (0; k_4) j F_{\xi} = \frac{H^4}{3} h_j(0; k_1) (0; k_2) (0; k_3) (0; k_4) j F_{\xi} ;
\]

This constitutes one of the main results of this work.

The total trispectrum of \( \xi \) is the sum of the contributions coming from both of the diagrams of \( \text{Fig.}\ \text{[3]} \) as

\[
h_j(0; k_1) (0; k_2) (0; k_3) (0; k_4) j F_{\xi}^{\text{total}} = h_j(0; k_1) (0; k_2) (0; k_3) (0; k_4) j F_{\xi}^{\text{1}} + h_j(0; k_1) (0; k_2) (0; k_3) (0; k_4) j F_{\xi}^{\text{2}} ;
\]
From the previous result one can read the order of magnitude of the total trispectrum and it agrees with the discussion of subsection IIIA. Moreover, one can also read the exact momentum dependence of the trispectrum. In the next section we shall study the shape of the trispectrum in more detail. In particular, we will consider the so-called equilateral configuration and we shall calculate the value of the non-linearity parameter $N_{L}$.

IV. $N_{L}$ AND THE SHAPE OF THE TRISPECTRUM IN THE EQUILATERAL CONFIGURATION

In this section, we will calculate the non-linearity parameter $N_{L}$ in the limit where all the four momentum vectors have the same magnitude. This is the so-called equilateral configuration used in previous works [22, 63]. If we denote the angle between $k_1$ and $k_2$ by $\theta_{ij}$, then in this configuration, we have $\cos(\theta_{12}) = \cos(\theta_{13}) = \cos(\theta_{23}) = 0$. The momentum dependence of the trispectrum is given by

$$G(x) = \frac{1}{2} \left( \frac{\partial^2 G_{nl}}{\partial k^2} \right) (x) = \frac{9}{25} \frac{\partial G_{nl}}{\partial k} (x);$$

where $G(x)$ denotes the first order curvature perturbation (gaussian random variable), $G_{nl}(x)$ denotes the average of $G_{nl}$. The trispectrum calculated in the present work results from quantum correlations around horizon crossing and does not admit a simple parametrization in terms of momentum independent non-linearity parameters as [66].

In the next subsections, we will adopt a naive parametrization for the trispectrum as

$$h(k_1,k_2,k_3,k_4) = \frac{4}{H^2} \Gamma(k_1;k_2;k_3;k_4) \left( \frac{\partial G_{nl}}{\partial k} \right) (x);$$

where $\Gamma$ is related to the trispectrum of $N_{L}$ as

$$h(k_1,k_2,k_3,k_4) = (2)^3 (3) \Gamma(k_1;k_2;k_3;k_4);$$

In general, $N_{L}$ defined by the previous expression will be shape dependent. For instance, this will be the case for the contact interaction trispectrum. Only for $N_{L}$ less than the form [37] will $N_{L}$ be a constant, i.e. shape independent. If one fully specifies the momentum vectors configuration, then $N_{L}$ becomess just a number. This seems to be the approach followed by several authors in the literature and in the next subsections we shall do the same to obtain the order of magnitude of the trispectrum. However, we should emphasize that the full trispectrum contains much more information than the one that can be described by just a number like $N_{L}$ and that this parametrization might not be so adequate to describe the information encoded in a general trispectrum.

A. $N_{L}$: general model

For the general model [1] and for an angular configuration like $\cos(\theta_{12}) = \cos(\theta_{13}) = \cos(\theta_{23}) = 1$, the contact interaction trispectrum gives a non-linearity parameter as

$$N_{L} c_1 = \frac{4}{H^2} \frac{\partial G_{nl}}{\partial k} (x);$$

where the different values of $N_{L}$ correspond to the three terms in the contact interaction trispectrum Eq. [22].
The scalar exchange trispectrum gives values for \( n_L \) as

\[
\begin{align*}
S_{\text{NL}}^{SE} &= 0.5 \frac{H^2}{P_{\Lambda}^2} A^2; & S_{\text{NL}}^{SE} &= 1.5 \frac{H^2}{P_{\Lambda}^2} A B; & S_{\text{NL}}^{SE} &= 2.5 \frac{H^2}{P_{\Lambda}^2} B^2; \\
\end{align*}
\]

where \( S_{\text{NL}}^{SE} \), \( S_{\text{NL}}^{SE} \), and \( S_{\text{NL}}^{SE} \) correspond to the values of \( n_L \) calculated from the terms in (28) proportional to \( A^2, B^2 \) and \( A B \) respectively.

\[ \text{C.} \quad n_L: \text{DBI-in action} \]

In order to give numerical results for \( n_L \), one has to choose a particular model which will determine the parameters \( i, A \) and \( B \). In this subsection, we particularize the results (41) and (42) for the DBI-in action model at leading order in the small sound speed.

The total \( n_L \) coming from the scalar exchange trispectrum is

\[
S_{\text{NL}}^{DBI} = S_{\text{NL}}^{SE} + S_{\text{NL}}^{SE} + S_{\text{NL}}^{SE} \quad 0.60 \frac{H^2}{P_{\Lambda}^2} \cdot \frac{C_3^2}{c_s^4}.
\]

1. Contrary to what happens in the case of the bispectrum, the equilateral configuration conditions do not x all degrees of freedom (dof) required to describe the shape of the trispectrum and we are left with two angular dof.
This result should be summed with $N_L \text{ coming from the contact interaction trispectrum}$ [25]

$$N_{DLBI} = N_{CI} \left( \frac{0.04}{c_s^2} \right)$$ (44)

For this particular configuration the magnitude of $N_{DLBI}^{SE}$ is more than one order of magnitude higher than $N_{DLBI}^{CI}$. We conclude that the total non-linearity parameter $N_L$ for DBI-inflation in the equilateral configuration with equal angles between the momentum vectors is

$$N_{DLBI}^{equi} \left( \frac{0.56}{c_s^2} \right)$$ (45)

V. CONCLUSION

In this work we have computed the connected four-point function of the primordial curvature perturbation at leading order in the slow-roll expansion and in the small sound speed limit for a generic model of kinetically driven inflation. This four-point correlation is coming from either via the exchange of a scalar mode or by a four-keg contact interaction at a point. We showed that in general the scalar exchange correlation is as important as the contact interaction correlation previously calculated in the literature. So the final answer to be compared with observational data should include the sum of these two contributions.
We have studied the shape dependence of the trispectrum for the DBI-aton model in the equilateral configuration. The equilateral limit conditions do not completely define the configuration of the four moment vectors and we are left with two remaining angular degrees of freedom. We have shown that the trispectrum is maximized when the angles between the four different moment vectors are equal to arccos(1/3) \text{ rad.} We found that for this 'maximal' equilateral configuration the non-linearity parameter for DBI-aton model is about one order of magnitude larger than the existing result in the literature that only takes into account the contact interaction diagram. Our numerical result for the non-linearity parameter for the DBI-aton model is \( N_L^{\text{DBI}} = 0.56 \). We did not prove that the maximum of the trispectrum occurs for the equilateral configuration. But we gave some evidence in Appendix B. In general there are five parameters to characterize the shape of the trispectrum. It would be desirable to explore, possibly numerically, all configurations to show that the maximum of \( N_L \) lies in the configuration we found. Also it is necessary to construct an estimator to extract information from CMB anisotropies. We will leave these issues for future investigations.

Note added: On the day this work was submitted, the paper [7] appeared in the arXiv, which contains some similar results.

Acknowledgements

We would like to thank Filippo Vernizzi for interesting discussions. We thank Takashi Hiramatsu for pointing out some typos in an early version of the manuscript. FA and SM are supported by the Japanese Society for the Promotion of Science (JSPS). KK is supported by RCUK, STFC and ERC. The authors thank the Yukawa Institute for Theoretical Physics (YITP) at Kyoto University. Discussions during the YITP workshop YITP-09-01 on 'Non-linear cosmological perturbations' were useful to complete this work. KK’s visit to the Yukawa Institute was supported by the Royal Society International Joint Project grant. We also thank the Institute for the Physics and Mathematics of the Universe (IPMU) for organizing the workshop entitled ‘Focus week on non-Gaussianities in the sky’ during which we had several important discussions about this work. SM is grateful to the ICG, Portsmouth for their hospitality when this work was completed.

Appendix A: Canceling the apparent divergences of the trispectrum in the equilateral limit

In the configuration where all the moment vectors have equal magnitude, i.e. the equilateral configuration, the variable \( C \) defined as the sum of the argument parts of the \( F_1 \) functions vanishes for the terms in (28) that contain a \( F_1 \) function with three negative argument parts. Because \( C \) appears in the denominator of some fractions in the definition of \( F_1 \), one might naively think that the trispectrum diverges in these configurations. We will now show that when considering all the 23 permutations in (28), the powers of \( C \) that appear in the denominator in the different terms cancel out and we are left with expressions that are clearly finite in the limit \( C \) going to zero.

The proof is rather simple if one notes that the apparently divergent terms \( F_1 \), functions with three negative argument parts, can be gathered in certain combinations that are clearly finite in the equilateral limit.

For example, if we take all the different terms containing \( F_1 \), we nd pairs of terms like

\[
F_1( k_1; k_2; k_3; k_4; i k_{ab}) + F_1( k_1; k_2; k_3; k_4; i k_{cd})
\]

where the only di erence from the rst term to the second is that \( k_2 \) and \( k_4 \) have changed position with \( k_3 \) and \( k_4 \). Hence the above two terms cancel for any of the four moment vectors \( k_1 \), \( k_2 \), \( k_3 \), \( k_4 \) and \( k_{ab} = k_{cd} \). To complete the proof, one just needs to show that this combination is finite in the equilateral limit. A simple algebraic one can show that

\[
F_1( k_1; k_2; k_3; k_4; i k_{ab}) + F_1( k_1; k_2; k_3; k_4; i k_{cd}) = 4 \frac{N L^{\text{DBI}}}{k_2} k_3 k_2 k_1 k_2 + \frac{1}{A_1 A_2^2};
\]

where \( A_1 = (k_2 + k_3 + k_4) \) and \( A_2 = (k_2 + k_3 + k_4) \). The r.h.s. of the previous equation is clearly finite in the limit \( C \to 0 \).

The proof of finiteness for the remaining divergent terms containing \( F_1 \) and \( F_4 \) in (28) is compl etely analogous to the proof just described but now one has to use the following combinations of terms.

\[
F_3( k_1; k_2; k_3; i k_{ab}; i k_{cd}; i k_{ef}) + F_4( k_1; k_2; k_3; i k_{ab}; i k_{cd}; i k_{ef})
\]

\[
= \frac{2 N L^{\text{DBI}}}{k_2} k_3 k_2 k_1 k_2 + \frac{1}{A_1 A_2^2} \frac{1}{A_1^2 A_2};
\]

\[\text{Equilateral Limit} \]

where \( A_1 = (k_2 + k_3 + k_4) \) and \( A_2 = (k_2 + k_3 + k_4) \). The r.h.s. of the previous equation is clearly finite in the limit \( C \to 0 \).

The proof of finiteness for the remaining divergent terms containing \( F_1 \) and \( F_4 \) in (28) is complementarily analogous to the proof just described but now one has to use the following combinations of terms.
Finally, all divergent terms containing \( F_2 \) can be completely written in terms of the following combinations:

\[
F_2( k_a; k_b; k_c; k_d, k_{ab}) = \frac{N c_k^2}{H^2} \left( \frac{l_1 A_2}{k_a k_b k_c k_d} \right) A_1 A_2^2 + \frac{1}{A_1 A_2} \frac{k_{ab} k_{cd}}{A_1 A_2^2} + \frac{k_d + k_{ab}}{A_1 A_2^2} ;
\]

(A 3)

All of these combinations are finite in the equilateral limit and all apparently divergent terms in the scalar exchange trispectrum \( [23] \) can be written in terms of these combinations. This implies that the trispectrum \( [23] \) is also finite in this limit as expected.

APPENDIX B: WHERE DOES THE MAXIMUM OF THE TRISPECTRUM FOR THE DBI-INFLATION MODEL Lie?

It seems difficult to pursue an analytical answer for this question. The main reason is the fact that we needed degrees of freedom to parametrize the shape of the trispectrum and the expression for the trispectrum, Eq. [35], is fairly complicated. Numerical searches for the maximum in the full parameter space are possible even with such a large parameter space to explore. We leave this for future work.

In this Appendix, we will relax the condition of equilateral configuration, allowing for two of the moment vectors to have a different magnitude from the others and we will show that the maximum that we found in subsection IV B is still a maximum of \( N \). This provides some evidence that this particular configuration maximizes \( N \).

Before we show the results, it is interesting to consider analytically certain limiting configurations such as the squeezed limit or in the case of the scalar exchange diagram the counter-collinear limit. These limits give us other indications about where the maximum of the trispectrum might lie. Also, because these limits can be obtained using different methods from the one used in this work, they provide consistency checks with our analytical results.

As first pointed out by Maldacena \( [4] \) and Seery et al. \( [63] \), all higher order correlators of a single elliptically obey consistent relations in the squeezed limit, i.e., when one of the moment vectors is very small. Let us consider the limit \( k_1 \to 0 \), which implies that the corresponding mode \( k_1 \) leaves the horizon well before all other modes leave the horizon. By the time the remaining modes exit the horizon, \( k_1 \) will be frozen as a super-horizon mode and is thus expected to deform the background. Following the algebra with some care, one finds the following relation for the trispectrum \( [63] \):

\[
h (k_1) (k_2) (k_3) (k_4) ; \quad F (k_1) \frac{d}{dt} h (k_2) (k_3) (k_4) ;
\]

(B 1)

in the limit \( k_1 \to 0 \). Using the fact that the bispectrum is \( B \) \( c_s^2 P^2 \) it follows that in the squeezed limit it according to [41] the trispectrum is \( O (c_s^2 P^3) \). Comparing this result with the full trispectrum, Eq. [35], which is of order \( 3 \), one finds that the total non-linearity parameter \( N \) calculated from [35] should be at most of order \( c_s^2 \) (i.e., under our approximation it should vanish) when any of the moment vectors goes to zero. We verified that this is
In Fig. 6, we plot the non-linearity parameter \( t \) versus angular dof to these with the three different contributions coming from the terms in (28) that are proportional to \( \alpha \), \( \beta \), and \( \alpha \beta \) respectively.

Explicitly, they are given by

\[
\mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{A \beta} = (2) \frac{1}{c^2} (k) \frac{1}{c^2} D_1(k_{12} = k) F^2(k) F(k_{12}) + 2 \text{ permutations};
\]

The case for 33. This would mean that the maximum of \( N_L \) might lie near the equilateral configuration.

As an example, we considered configurations where the two momentum vectors \( k_1 \) and \( k_2 \) have different magnitude \( q \) from the magnitude of \( k_1 \) and \( k_2 \) that we normalized to unity. Then in this configuration, we have

\[
\cos(1) \cos(13) \cos(14) = \cos(15) \cos(24) \cos(2) \cos(12) = q^2 (1 + \cos(3))^2.
\]

The moment momentum conservation in planes \( \cos(3) = (1-q)(\cos(1)+\cos(2)) \). We also allow one of the angular dof to vary freely, the other angular dof is fixed by \( \cos(1) = 1 \) to the value that gives us the maximum we found in subsection IVB.

In Fig. 6, we plot the non-linearity parameter \( N_L \) for the DBI-in action model. From the momentum conservation, \( \cos(2) \) is restricted to \( \cos(2) = 1 \). Also, we restricted all angles \( q < 1 \) can be related to those with \( q = 1 \) by rescaling \( k_1 \) and \( k_2 \). The left panel shows the contribution from the contact interaction. In the right panel, we plot the total \( N_L \). As can be seen in the right panel of Fig. 6, the maximum of \( N_L \) occurs exactly for the equilateral configuration when all the angles \( 1, 2 \) and \( 3 \) are equal. This provides evidence that the maximum of the non-linearity parameter would happen for this configuration.

APPENDIX C: THE DBI SCALAR EXCHANGE TRISPECTRUM IN THE EQUILATERAL LIMIT

In this Appendix, we present the scalar exchange trispectrum of the primordial curvature perturbation for the DBI-in action model in the equilateral configuration. These analytical expressions can be derived from the general expression for the scalar exchange trispectrum, Eq. 28. We will use these simpler equations to calculate the non-linearity parameter \( N_L \) in subsection IVB and to study the shape dependence of the trispectrum in subsection IVB.

At leading order in the small sound speed and in the slow-roll expansion, the scalar exchange trispectrum for the DBI-in action model is

\[
\mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{A \beta} = \mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{A \beta} + \mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{B \beta} + \mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{A \beta} \tag{C1}
\]

where the three different contributions come from the terms in (28) that are proportional to \( A^2 \), \( B^2 \), and \( AB \) respectively.

Explicitly, they are given by

\[
\mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{A \beta} = (2) \frac{1}{c^2} (k) \frac{1}{c^2} D_1(k_{12} = k) F^2(k) F(k_{12}) + 2 \text{ permutations}; \tag{C2}
\]

\[
\mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{B \beta} = (2) \frac{1}{c^2} (k) \frac{1}{c^2} D_1(k_{12} = k) F^2(k) F(k_{12}) + 2 \text{ permutations}; \tag{C2}
\]

\[
\mathcal{H} \mathcal{J}(0; k_1) (0; k_2) (0; k_3) (0; k_4) j \, \mathcal{E}^E_{A \beta} = (2) \frac{1}{c^2} (k) \frac{1}{c^2} D_1(k_{12} = k) F^2(k) F(k_{12}) + 2 \text{ permutations}; \tag{C2}
\]
\[ D_1(x) = \frac{9x^4(3x^3 + 36x^2 + 176x^3 + 432x^2 + 528x + 512)}{2^6(x + 2)^6}; \]
\[ D_2(x) = \frac{3x(13x^3 + 156x^2 + 748x^2 + 1696x^1 + 1072x^3 + 160x^2 + 1172x + 8192)}{2^6(x + 2)^6}; \]
\[ D_3(x) = \frac{103x^3 + 1236x^2 + 5276x^7 + 5632x^6 + 27052x^5 + 95248x^4 + 69376x^3 + 149056x^2 + 281792x + 131072}{2^9(x + 2)^9}; \]

where we have defined three \( D_i(x) \) functions, with \( i = 1; 2; 3 \), as

\[ k_{12} = k^p 2(1 + \cos \phi_1), k_{13} = k^p 2(1 + \cos \phi_2) \text{ and } k_{14} = k^p 2(1 + \cos \phi_3). \]

\( k \) denotes the com mon amplitude of all four momentum vectors \( k_i \), with \( j = 1; \ldots; 4 \) and the rescaled power spectrum is \( P(k) = H^2 = (4\pi k^3) \) that should be evaluated at horizon crossing.
