(Dated: August 3, 2013)

The principle of electric-magnetic duality states that electric and magnetic fields must be treated on equal footing. If it implies that one must consider both electric and magnetic sources in the Maxwell equations.

When the dimension of the electric source is increased, the dimension of the dual magnetic source decreases. In the extreme case of an electric object whose worldvolume has dimension D-2, in D spacetime dimensions, the worldvolume of the corresponding magnetic object has dimension zero. The worldvolume is just a point. We shall say then that the magnetic source is an event. The simplest example of an event is the dual of an ordinary point electric charge in D = 3 spacetime dimensions. Endowing such an object with dynamical properties seems to be a contradiction in terms. Thus, so far, events have been considered as external sources. This is unsatisfactory because it violates the principle of action and reaction: the source acts on the electromagnetic field, but the field does not react on the source. In order to have a closed physical system one must, therefore, assign dynamics to the source. A way to achieve this is the following: One considers the event as the imprint of a \textit{ux}-carrying particle which comes in from an extra dimension, hits spacetime and spreads its \textit{ux} over it. It will be shown below that this idea can indeed be carried through successfully.

The idea uses two key ingredients: (i) The electromagnetic field must be localized on a D = 3 slice of a higher-dimensional spacetime, and in addition (ii) magnetic \textit{ux} can escape in the extra dimensions where it is carried by point-like particles. Two examples in which these ingredients appear present include the \textit{ux} in brane of \textit{M} theory and \textit{SU}(2) Josephson junctions. We will identify dynamical events in these familiar systems.

Solving in this way the problem of the dynamics of a point source in spacetime opens a treasure chest. A point event is the simplest member of a family which includes also extended events. An extended event is the imprint left on spacetime when a p-brane with p = 1 hits it. Just as point events, extended events do not obey an equation of motion in the D-dimensional spacetime, because their dynamics takes place in the extra dimensions. This is the key difference between events and particles, or ordinary extended objects. For example a closed one-dimensional event is a loop in the D-dimensional spacetime with arbitrary shape, it can be timelike, spacelike, null or a combination of all three. It can also go forward and backwards in time with no violation of causality. The worldline is not a history. However it still produces \textit{ux} in the D-dimensional spacetime and interacts with them in a closed physical system.

It is the main point of this article to put forward the idea that events should play a central role in physics as that played by particles or ordinary branes. It should be stressed here that events occur in Lorentzian spacetime and should be distinguished from instantons, i.e. solutions of the Euclidean equations that describe tunneling. This will become more clear at the end.

With no essential loss of generality we will restrict ourselves to the magnetic point events of D = 3 electrodynamics, which motivated the introduction of the concept. The generalization to extended events will be straightforward.

A simple action is the sum of three terms,

\begin{equation}
I = \frac{1}{2} R d^3x \Gamma \mathcal{F} \mathcal{F} + m_j d \mathcal{P} \mathcal{P} + \frac{g}{d^3x} \mathcal{I}_1(x, z)(x) \,.
\end{equation}

Here $\mathcal{F} = \partial' \mathcal{A}$ with the magnetic potential, and $z^\mu(\cdot)$ is the worldline of the \textit{ux}-carrying particle coming in from the past and absorbed at $t = 0$. The coordinates of the event are, in self-explanatory notation, $z^\mu(0) = (z, 0)$. The third axis runs along the extra dimension and the signature is $(+, +, +)$. For a particle being emitted (an inverse event) one should reverse the
lim its of the integration as well as the sign of g.

The equation of motion for \( \gamma \) reads

\[
\gamma = g \theta^{(3)}(x, z),
\]

(2)

The general solution of (2) is the sum \( \gamma = \gamma_0 + gG \), where \( \gamma_0 \) is the general solution of the homogeneous equation \( g = 0 \) and \( G \) is a Green function of the wave operator.

At the classical level a natural choice is to take for \( G \) the retarded Green function which vanishes outside the future light cone of the event,

\[
G_R(x) = \frac{1}{2} \frac{1}{x \cdot x} \delta(x^0) \quad (x \cdot x > 0)
\]

(3)

where we have here set \( z = 0 \). If one takes \( \gamma_0 = 0 \) the situation as seen from within the \( D = 3 \) spacetime is the following: For \( x^0 < 0 \) there is no \( \gamma \). At \( x^0 = 0 \), suddenly a flash of light emerges and propagates to the future [2]. This situation will be the most probable classically because it corresponds to a \( u^0 \)-carrying particle in pining from the extra dimension, without any precise control \( (\neq \text{tuned}^\dagger) \) of its initial conditions [3].

The time-reversed process, where one would replace the retarded Green function \( G_R \) by the advanced one \( G_A \); corresponds to a precisely prepared \( (\neq \text{tuned}^\dagger) \) pulse of radiation converging on the spacetime point \( z = 0 \), and disappearing as a \( u^0 \)-carrying particle into the extra dimension. This situation would be classically improvable.

The action (1) is not fully satisfactory because it does not allow a proper treatment of energy-momentum balance. Firstly, the energy of the event \( \gamma \) diverges. In order to make it finite one must smear the magnetic source over a wide region of the \( D = 3 \) spacetime. This smearing should be physically related to the approach and absorption of the \( u^0 \)-carrying particle at \( z = 0 \). There appears to be no natural description of this process, consistent with Poincare invariance, within the present simple effective model. We therefore prefer to leave the issue of energy-momentum conservation to an eventual underlyng microscopic theory. A more analogous difficulty actually arises when one tries to compute the mass of a magnetic particle within the Dirac theory.

A more satisfactory situation is encountered in connection with the conservation of magnetic \( u^0 \) and of angular momentum. The action (1) is invariant, up to a surface term, under the global gauge transformation \( \gamma \to \gamma + c, \) where \( c \) is a constant. The first two terms of (2) are obviously invariant, so one needs to analyze only the change in the third, coupling term. This is just \( g \) times the shift \( c \). In order to apply Noether's theorem one now resizes this change as c times the integral over the extended spacetime of the divergence of a current, i.e.

\[
I = c \int d^4 x \theta_0 \left( \frac{Z_0}{1} \right) J_{\text{particle}}^M \theta_0 \quad \text{where}
\]

\[
J_{\text{particle}}^M = g \int d^4(x, z) \left( \frac{Z_0}{1} \right) \frac{d^2x}{d}.
\]

(4)

It is easy to verify that \( \theta_0 J_{\text{particle}}^M = g \delta_3(\alpha, z) \); and \( d^3x J_{\text{particle}}^0 = g (z^0, x^0) \) with the step function.

Furthermore, the contribution to the current from the Maxwell term is given by

\[
J_{\text{Ext}}^M = (1) \left( \theta_0 J_{\text{particle}}^0 \right) = 0.
\]

(5)

On account of the \( R \) equation (2), this obeys \( \theta_0 J_{\text{Ext}}^M = g \delta_3(\alpha, z) \). The divergence of the two currents cancel, and one obtains the conserved charge law \( \theta_0 (J_{\text{particle}}^M + J_{\text{Ext}}^M) = 0 \).

In conclusion, the conserved charge due to the (global) invariance of the action is the magnetic \( u^0 \) current, which is being transferred to the electromagnetic field by the pinning particle. Unlike the situation with energy and momentum, this field \( \phi \) is finite. It constitutes the main signature of the event, independent of any microscopic details.

The most striking consequence of the existence of magnetic events is the quantization rule for the product of the electromagnetic charge and of the event charge \( g \).

\[
e^g = 0 \quad \text{integer}.
\]

(6)

For the magnetic pole in 3+1 spacetime dimensions, this result was rst obtained by D. Ibr in 1931, and rederived by him in 1948 from the quantum mechanical invariance of a classical point-particle action principle. Later on D. Ibr's 1948 derivation was proven to remain valid for extended objects [2].

The quantization rule (3) has survived the embedding of the effective point-particle theory in detailed microscopic models. Since its derivation is independent of whether the electric and magnetic sources obey equations of motion or not, it remains valid for events of any dimension.

The fact that magnetic events imply the quantization of electric charge is, conceptually, even more striking than the analogous implication of magnetic poles. Indeed, for example in four-dimensional spacetime one could have in the whole history of the universe a single magnetic event, which could be a very small loop carrying a quantum of magnetic \( u^0 \). That small loop could lie entirely in the very far past (or, for that matter, in the very far future) and yet all electric charges, at all times, should have to be quantized according to (3). One could say that magnetic events are like the Cheshire cats; they vanish leaving only their smiles behind.

There exists one more property of magnetic events which, like the conservation of magnetic \( u^0 \) and the quantization rule of electric charge, is simple and universal, i.e. it is expected to survive in any underlying microscopic theory. This is angular momentum. Consider an electric particle with worldline \( \gamma \). The particle starts feeling the in uence of the event after it enters the future light cone. The conserved angular momentum is the sum of the orbital angular momentum of the electric particle, \( L \), and of the angular momentum stored in the electromagnetic field, \( \gamma_0 J_{\text{Ext}}^0 \).

The latter vanishes before the interaction, and it is given afterwards by

\[
\gamma J_{\text{Ext}}^0 = \frac{p \cap y}{y}.
\]

(7)
The electromagnetic field whose energy-momentum tensor enters in the expression for $J_{\text{eik}}$ is the sum of the retarded eik (3) of the magnetic event, and of the eik of the electric particle. The only contribution comes from the cross term. To evaluate the integral it is necessary to regularize the event eik on the light-cone. The result uses only the Gauss law and does not depend on the details of the regularization.

Since total angular momentum is conserved, the change in the orbital angular momentum of the particle is given by

$$L = \frac{1}{L} J_{\text{eik}}. $$

The dual pseudovector $L = \frac{1}{L} L$ points from the event to the electric charge and, in view of the quantization rule [8], its magnitude is an integer multiple of $\sim$,

$$J_L e = 2 = n \sim. $$

This result mirrors the well-known fact that, in 3+1 dimensions, the angular momentum stored in the eik of an electric and a magnetic charge is a multiple of $-2$.

As the last development in the context of the effective classical theory [1] of events, one may consider the addition of a Chern-Simons term to the Maxwell action. The modified Maxwell equations take the form

$$\theta F + F = j_{\text{el}} \quad \text{and} \quad \theta F = j_{\text{mag}}; \quad (9)$$

where $\theta$ is the coset element of the Chern-Simons group and we have here allowed for generic sources. Taking the divergence of the left-hand equation gives $\theta j_{\text{el}} = j_{\text{mag}}$. Hence, a magnetic event deposits a topologically g units of electric charge. Furthermore, since this latter is quantized, one concludes that $\theta j_{\text{el}}$ must be an integer multiple of $2 - e^2$. It is worthwhile noting here that the presence of magnetic events in a Chern-Simons theory is a result of the non-perturbative Chern-Simons term,

$$\text{as expressed by the non-vanishing expectation value of a complex scalar field, } h i = j_{\text{el}} s^2. $$

By using dimensional reduction and the Witten effect, one may acquire the electric charge in the presence of a topological -term. One arrives at the same conclusion without having to dimensionally reduce the theory, along lines that generalize the analysis in 2+1 dimensions. The argument in D = 2+1 dimensions uses n extended events whose codimension spans the entire space.

So far we have dealt with universal properties of events as described by a simplified effective theory. Next we will exhibit two exam ples of their occurrence in in stances where the underlying microscopic theory already exists.

The first example is the impinging of D-particles on D2-branes in string theory. The Maxwell eik lives on the worldvolume of the D2-brane, which is in turn embedded in a ten-dimensional spacetime [11]. Bulk D-particles feel the gravitational attraction of the D2-brane, but this is negligibly weak at distances $\ell_s$, the characteristic string length. However, whenever a D-particle gets sufficiently close to the D2-brane, a tachyonic instability develops [12] and it gets rapidly absorbed. To observe on the D2-brane the process looks precisely like a magnetic event: the particle deposits a uw $F = T_0 = T_2$, which spreads at the speed of light. Here $T_0$ is the mass of the D-particle and $T_2$ is the tension of the D2-brane. If one normalizes canonically the photon eik the magnetic charge of the event is $e = T_0 = T_2$. The minimal electric charge, which corresponds to the endpoint of an open string, is given by $e = T_0 = T_2$, where $T_0 = 2 T_2$ is the fundamental string tension. Using Polchinski’s values for the tensions [11], one then finds $e = 2 = \sim e$. The capture of a D-particle corresponds, indeed, to a magnetic event with the minimal allowed charge.

One may view the impinging D-particle as a small spherical D2-brane carrying one unit of magnetic flux. Events and inverse events acquire then a geometric meaning as the joining and splitting of magnetic branes. It is of some interest to induce magnetic events by inserting one (or more) D8-branes between the D2-brane and the Minkowski vacuum [12]. When the D-particle traverses a D8-brane an open string stretching between them is automatically created [13]. A firer D-particle has been dissolved, these open strings remain attached to the D2-brane. They are the electric charges deposited by the event. All universal features of events are, thus, neatly illustrated in this string theory example.

Our second example is taken from the theory of superconductivity. The setup is that of a S-I-S Josephson junction, consisting of a thin insulating layer sandwiched between two superconducting bulk pieces. The (history of the) insulating layer will be our D = 3 spacetime, while the adjacent (history of the) superconductor will be the extended spacetime. This setup was proposed in [15] as an example of ‘localization’ of the Maxwell eik. To see why, recall that the superconductor may be described as a topological -term as expressed by the non-vanishing expectation value of a complex scalar field, $h i = j_{\text{eik}} s^2$. This condensate screens all electric charges and expels the magnetic eik from the bulk. The longitudinal electric eik and the normal magnetic eik continue to vanish inside the insulating layer, while the remaining non-zero eik can be identified as those of the effective D = 3 electrodynamics.

$$F = F^1 = 1 \quad F = F^2 $$

Here the math-style and text-style symbols denote the three- and four-dimensional eikons. The latter are evaluated at the position $x^3 = 0$ of the junction, which is sufficiently thin so as to neglect, in its interior, all eik variations along the $x^1$ direction. Notice that the identification [17] has exchanged the roles of ‘electric’ and ‘magnetic’.
The \textit{m}agnetic\ events of the D = 3 theory correspond to electric charges crossing the insulating layer. This follows from \cite{10} and the Maxwell equation \( E^3 = J \). Integrating over the junction gives, for an isolated system, the conserved global charge \( \oint \mathbf{E} \cdot \mathbf{d} s = Q_{\text{right}} \), where \( Q_{\text{right}} \) is the charge in the right-hand side of the junction. The \textit{m}agnetic\ \( u_x \), deposited by the event is therefore equal to the total electric charge transferred.

The effective D = 3 theory has also \textit{electric}\ point-like charges if the superconductors are of type II. These charges are the endpoints of Abrikosov vortex tubes which spread their magnetic \( u_x \) in the insulating layer. The quantum of \( u_x \), \( \hbar = Q_{\text{right}} \), is the \textit{electric}\ charge in three dimensions. The quantization condition \( \mathbf{c} \) is thus valid, provided the charge carriers crossing the junction are Cooper pairs \cite{11}.

The most striking feature of a Josephson junction is the existence of a \textit{Josephson} current at zero voltage drop \cite{11}. This arises because of the quantum tunneling of Cooper pairs across the insulating layer. The effect is described mathematically by instantons, which are the solutions of equation \( \mathbf{c} \) in imaginary time. The action of an instanton controls the strength of the Josephson current, \( J^2 = J_{\text{Jax}} \sin \left( \theta - \theta_{\text{Jax}}^0 \right) \) with \( J_{\text{Jax}} \) the \textit{electric}\ charge in three-dimensions, \( \theta, \theta_{\text{Jax}}^0 \), as well as the non-perturbatively \textit{electric}\ charge of \( \theta \) in the effective three-dimensions.

A closely-related, instantons should be distinguished from real-time events, which of the two is more relevant depends on the detailed physical context. The example of the D2-brane in string theory helps to illustrate clearly this point: an event describes the capture of a D-particle, whereas instantons describe the tunneling of \( u_x \) from a neighboring D-brane. Thus, an observer living on a D2-brane in a D-particle gas will witness numerous real-time events, but there will be no tunnelings if there is no other D-brane nearby.

We conclude by remarking that, even though superconductivity makes events tangible, the more striking implications of their existence might reside in astrophysics and cosmology. The ideas of this letter cannot, however, be simply transposed to gravity. Nevertheless, the distinction between instantons and events acquires special meaning in cosmology: as our Universe created out of nothing, by quantum tunneling, or was the Big Bang an extended (and most dramatic) event? \cite{12}

Aknowledgments. \( \mathbf{w} \) e would like to thank Roland Cbounds, Denis Bernard and Jan Troost for useful discussions. C. Bunsen thanks Vivian Scharrer for her essential assistance in the preparation of the manuscript. C. Bunsen and M.
