Theory of Neutrino Masses and Mixing

Walter Grimus

University of Vienna, Faculty of Physics, Boltzmanngasse 5, A–1090 Vienna, Austria

Abstract
We motivate the usage of finite groups as symmetries of the Lagrangian. After a presentation of basic group-theoretical concepts, we introduce the notion of characters and character tables in the context of irreducible representations and discuss their applications. We exemplify these theoretical concepts with the groups $S_4$ and $A_4$. Finally, we discuss the relation between tensor products of irreducible representations and Yukawa couplings and describe a model for tri-bimaximal lepton mixing based on $A_4$.

1 Introduction
Motivation for horizontal symmetries: The mass spectrum of quarks and leptons is one of the least understood facts of particle physics. However, it was noticed quite early [1] that the Cabibbo angle might be a function of the ratio of down and strange quark mass because numerically one has

$$\sin \theta_c \simeq \sqrt{\frac{m_d}{m_s}}. \quad (1)$$

A very popular possibility to generate fermion masses and mixing is the Higgs mechanism. This has brought about the idea that in such a framework the CKM matrix could be explained by symmetries acting on the three quark families which restrict the Yukawa couplings such that a relation like equation (1) becomes possible. Since the CKM matrix is not far from the unit matrix and the up and down quark mass spectra are strongly hierarchical, it seems at least plausible that the mixing angles are functions of quark mass ratios.

1Lecture presented at IV International Pontecorvo Neutrino Physics School, September 26 – October 6, 2010, Alushta, Crimea
The observation by Harrison, Perkins and Scott \cite{2} that lepton mixing is in good approximation *tri-bimaximal*, i.e. compatible with the mixing matrix
\[
U \simeq \begin{pmatrix}
\frac{2}{\sqrt{6}} & \frac{1}{\sqrt{3}} & 0 \\
-\frac{1}{\sqrt{6}} & \frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{2}} \\
-\frac{1}{\sqrt{6}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}}
\end{pmatrix} \equiv U_{\text{HPS}},
\tag{2}
\]
has given a boost to the idea of family symmetries. In the lepton sector it seems that mixing angles could be related to “pure numbers.” At any rate, $U$ is very different from the unit matrix and thus lepton mixing is very different from quark mixing \cite{3}.

**Neutrino mass spectrum:** The idea that the elements of $U$ are, in good approximation, pure numbers (and not functions of lepton mass ratios) is in accord with the observation of the neutrino mass spectrum: it is either completely different from the charged-fermion mass spectra or its hierarchy is not so pronounced \cite{3}.

We know from neutrino oscillations that the neutrino mass spectrum is non-degenerate. The neutrino mass spectrum is called hierarchical, if $m_1 \ll \Delta m^2_{\odot}$, where $m_1$ is the smallest neutrino mass and $\Delta m^2_{\odot}$ the solar mass-squared difference. Since $\Delta m^2_{\text{atm}}/\Delta m^2_{\odot} \sim 30$ we conclude that $m_3/m_2 \simeq \sqrt{\Delta m^2_{\text{atm}}/\Delta m^2_{\odot}} \sim 5\div6$ in the hierarchical case which illustrates that a neutrino mass hierarchy can only be rather weak. The quantity $\Delta m^2_{\text{atm}}$ is the atmospheric mass-squared difference. An inverted hierarchy is also possible if (by the usual convention) $m_3$ is the smallest mass with $m_3 \ll \Delta m^2_{\text{atm}}$. Experimentally, the question of the neutrino mass spectrum is completely undecided. If the smallest neutrino mass is denoted by $m_s$ we have a *normal* ordering for $m_s = m_1$ and an *inverted* ordering for $m_s = m_3$. The spectrum

![Diagram](attachment:image.png)
is called quasi-degenerate if \( m_1 \simeq m_2 \simeq m_3 \). Of course, also a spectrum between hierarchical and quasi-degenerate is allowed for both orderings.

**Neutrino mass terms and parameter counting:** In the following we assume that
- neutrinos have Majorana nature and
- the charged-lepton mass matrix is diagonal.

Majorana neutrinos are theoretically more appealing than Dirac neutrinos because many mechanisms for neutrino mass generation, e.g. the seesaw mechanism \([4]\), naturally lead to Majorana nature. The second assumption is used only for the time being for the purpose of parameter counting.

A Majorana neutrino mass term is given by

\[
\mathcal{L}_{\text{Maj}} = \frac{1}{2} \nu_L^T C^{-1} \mathcal{M}_\nu \nu_L + \text{H.c.}
\]

with the charge-conjugation matrix \( C \). From the anticommutation property of the neutrino fields we conclude that \( \mathcal{M}_\nu = \mathcal{M}_\nu^T \), i.e. \( \mathcal{M}_\nu \) is a symmetric but in general complex matrix. For the transformation to the mass eigenfields, the following theorem, specialized to \( 3 \times 3 \) matrices, is applied.

**Theorem 1** (Schur). For every complex, symmetric matrix \( \mathcal{M}_\nu \) there exists a unitary matrix \( U \) with \( U^T \mathcal{M}_\nu U = \text{diag}(m_1, m_2, m_3) \) and \( m_j \geq 0 \).

The matrix \( U \) diagonalizing the neutrino mass matrix \( \mathcal{M}_\nu \) is called the Pontecorvo–Maki–Nakagawa–Sakata (PMNS) or lepton mixing matrix, provided we are in a basis where the charged-lepton mass matrix is diagonal. The matrix \( U \) is usually parameterized as

\[
U = e^{i\hat{\alpha}} U_{23} U_{13} U_{12} \begin{diagonal} 1, e^{i\hat{\beta}_2}, e^{i\hat{\beta}_3} \end{diagonal}.
\]

The diagonal phase matrix \( e^{i\hat{\alpha}} = \text{diag} (e^{i\alpha_1}, e^{i\alpha_2}, e^{i\alpha_3}) \) is unphysical in the charged-current interaction because it can be absorbed into the charged lepton fields. The matrices \( U_{23} \), \( U_{13} \) and \( U_{12} \) are rotations in the subsectors indicated by their subscripts:

\[
U_{23} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_{23} & s_{23} \\ 0 & -s_{23} & c_{23} \end{pmatrix},
\]
In the mixing matrix the conventions $0^\circ \leq \theta_{ij} \leq 90^\circ$ are imposed. As a consequence, one must allow the full range $0^\circ \leq \delta < 360^\circ$ of the CP-violating CKM-type phase $\delta$. As for the neutrino masses, one imposes $m_1 < m_2$ with $\Delta m^2 = m_2^2 - m_1^2$. With this convention the sign of $m_3^2 - m_1^2$ is a physical quantity and must eventually be determined by experiment.

In summary there are nine physical parameters in neutrino masses and mixing: three masses, three angles and the three phases $\delta$, $\beta_2$ and $\beta_3$. The latter two phases are the so-called Majorana phases; if neutrinos have Dirac nature, they can be removed from the charged-current interactions by absorbing them into the neutrino fields.

Let us compare the number of nine parameters with the number of parameters in $M_\nu$. There are $6 \times 2 = 12$ real parameters in $M_\nu$. However, e.g. the first line and first column can be made real by a phase transformation $e^{i\hat{\alpha}}$ which has no effect in the charged current interactions—see above. Thus we have nine real physical parameters in $M_\nu$ corresponding to the nine physical quantities above. As mentioned before, there is also one discrete physical parameter, namely sign $(m_3^2 - m_1^2)$, which is $+1$ for the normal ordering and $-1$ for the inverted ordering of the neutrino mass spectrum.

Finally, we want to make some remarks concerning the diagonalization of $M_\nu$ with theorem $[\text{I}]$. If we write $U = (u_1, u_2, u_3)$ with an orthonormal (ON) basis $u_j$ of $\mathbb{C}^3$, theorem $[\text{I}]$ tells us that

$$M_\nu u_j = m_j u_j^*. \quad (8)$$

Note the following points:

- In general, $u_j$ is not an eigenvector of $M_\nu$, this is the case only for real $u_j$.
- If $\lambda$ is an eigenvalue of $M_\nu$, then $|\lambda|$ is in general not a neutrino mass.
- However, the neutrino masses can be obtained by $M_\nu^\dagger M_\nu u_j = m_j^2 u_j$.

In these lecture notes we will discuss some features of model building for lepton masses and mixing—see for instance $[5, 6]$ for reviews. However,
we will first delve into useful theoretical aspects of finite groups and review two groups popular in model building. For the general theory of groups we refer the reader e.g. to [7, 8]. Recent reviews on finite subgroups of SU(2) and SU(3) are presented in [9, 10], for more specialized recent reviews see [11, 12, 13].

2 Theory of finite groups

2.1 Basics

We assume familiarity of the reader with the very basic notions like the definition of a group, representation, irreducible representation (irrep), subgroup, coset and normal subgroup, which can be found in any textbook on group theory, e.g. in [7, 8].

Now we will explain some basic useful concepts. On a group $G$ one always has an equivalence relation via the following definition: $g_1$ is conjugate to $g_2$ if it exists a $g \in G$ such that $g g_1 g^{-1} = g_2$. The sets of equivalent elements are called conjugacy classes. Obviously, $\{e\}$ is a class consisting only of the unit element, and a normal subgroup consists of complete conjugacy classes.

Irreps and proper normal subgroups: Using a symmetry group in physics mostly boils down to applying its irreps to physical objects (multiplets). Therefore, we need to know the irreps or methods how to track them down. A good part of this section is devoted to this subject.

Knowing the proper normal subgroups of $G$ helps in this respect. The notion “proper” means that the subgroup is larger than $\{e\}$ and smaller than $G$. Let $H$ be a proper normal subgroup of $G$, then

- the mapping $f : g \in G \rightarrow Hg \in G/H$ is a homomorphism, i.e. the relation $f(g)f(g') = f(gg')$ holds $\forall g, g' \in G$,

- and any representation $D$ of $G/H$ induces naturally a representation $\bar{D}$ of $G$ via $\bar{D}(g) \equiv D(Hg)$.

Direct product: With two groups $G$ and $G'$ one can form the direct product group $G \times G'$ with the multiplication law $(g_1, g'_1)(g_2, g'_2) = (g_1 g_2, g'_1 g'_2)$. This is often used in model building. E.g., one has a symmetry group like the permutation group $S_3$ and enlarges it by a sign transformation leading to $S_3 \times \mathbb{Z}_2$, a direct product of $S_3$ with the cyclic group $\mathbb{Z}_2$. 

5
Semidirect product: This generalization of the direct product is written as \( H \rtimes G \), which symbolizes that \( G \) acts on \( H \) via the homomorphism \( \phi : G \to \text{Aut}(H) \) where \( \text{Aut}(H) \) is the group of automorphisms on \( H \). (An automorphism \( \phi \) on \( H \) is simply a group isomorphism \( \phi : H \to H \).) The multiplication law is given by

\[
(h_1, g_1)(h_2, g_2) = (h_1 \phi(g_1)h_2, g_1g_2).
\] (9)

This is a rather abstract definition and it takes a bit of effort to prove that the multiplication law is associative. We will shortly see that in practice it has a very simple interpretation.

Obviously, for \( \phi = \text{id} \) the semidirect product is identical with the direct product. A useful question for model building is if a group can be decomposed into a semidirect product. Actually, a closer examination of finite groups shows that semidirect products are ubiquitous! The reason is the following theorem.

**Theorem 2.** Let us assume that \( H \) is a proper normal subgroup of \( S \) and \( G \) a subgroup of \( S \) with following properties:

1. \( H \cap G = \{e\} \),
2. every element \( s \in S \) can be written as \( s = hg \) with \( h \in H \), \( g \in G \).

Then the following holds:

- \( S \cong H \rtimes G \) with \( \phi(g)h = ghg^{-1} \),
- the decomposition \( s = hg \) is unique,
- \( S/H \cong G \).

The proof is straightforward. That the homomorphism \( \phi \) has the form given in the theorem simply follows from the multiplication of two elements of \( S \):

\[
s_1s_2 = (h_1g_1)(h_2g_2) = (h_1g_1h_2g_2^{-1})(g_1g_2).
\] (10)

### 2.2 Symmetries in the Lagrangian versus symmetry groups

Suppose we have a multiplet of fermion fields \( \psi_1, \ldots, \psi_r \) in the Lagrangian \( \mathcal{L} \). Then \( \mathcal{L} \) has the form

\[
\mathcal{L} = i \sum_{j=1}^{r} \bar{\psi}_j \gamma^\mu \partial_\mu \psi_j + \cdots
\] (11)
where the dots indicate the terms beyond the kinetic terms. The symmetries of $\mathcal{L}$ are given by transformations $\psi_j \rightarrow A^{(p)}_{jk} \psi_k$ ($p = 1, \ldots, N_{\text{gen}}$). Since the kinetic term has to be invariant, it follows that the matrices $A^{(p)}$ ($p = 1, \ldots, N_{\text{gen}}$) are unitary. There are two approaches to symmetries and Lagrangians:

- We start with $\mathcal{L}$ and impose symmetries $A^{(p)}$ on $\mathcal{L}$. Then the $N_{\text{gen}}$ matrices $A^{(p)}$ generate a representation of a symmetry group $G$ from which we can infer the group $G$.

- We can also take the opposite point of view. We begin with a group $G$ and introduce multiplets of fields which transform according to representations of $G$. In this way we determine $\mathcal{L}$ from the symmetry group and the multiplets we introduce.

### 2.3 Useful theorems for finite groups

Finite groups, i.e., groups whose number of elements is finite, are very popular in model building. As expected, infinite groups are more complicated than finite ones: They possess infinitely many inequivalent irreps and non-compact simple Lie groups $G$ possess no finite-dimensional unitary irreps apart from the trivial ones where every element is mapped onto unity.

Let us for example consider $U(1)$ as the simplest infinite group. We readily find its irreps: $e^{i\alpha} \rightarrow e^{in\alpha}$ with $n \in \mathbb{Z}$. Thus there are infinitely many. The same applies to the simplest non-abelian group $O(2)$. Its irreps can be found, for instance, in the appendix of [14].

For finite groups the number of its elements is called order of $G$ and abbreviated by $\text{ord} \, G$. Finite groups have the following properties:

- They possess a finite number of inequivalent irreps,
- all irreps are equivalent to unitary irreps,
- and all numbers concerning properties of the group and its irreps are finite as well; this allows to derive extremely useful relations which are totally lacking in infinite groups.

Now we list some of the most important theorems for finite groups:

**Theorem 3 (Lagrange).** If $H$ is a subgroup of $G$, then $\text{ord} \, H$ is a divisor of $\text{ord} \, G$. 
This theorem has a straightforward corollary. Defining the order of an element \( g \) of \( G \) as the smallest number \( r \) such that \( g^r = e \), we observe that every element \( g \in G \) generates a cyclic subgroup \( \mathbb{Z}_r \subseteq G \). Therefore, the order of every element is a divisor of \( \text{ord} \, G \).

**Theorem 4.** If we denote the irreps of \( G \) by \( D^{(\alpha)} \), with \( \text{dim} \, D^{(\alpha)} = d_\alpha \) being the dimension of the vector space on which the irrep acts, and if the index \( \alpha \) numbers all inequivalent irreps, then it follows that

\[
\sum_\alpha d_\alpha^2 = \text{ord} \, G. \tag{12}
\]

**Theorem 5.** The number of inequivalent irreps \( D^{(\alpha)} \) equals the number of conjugacy classes of \( G \).

### 2.4 Characters and character tables

**Orthogonality relations for irreps:** One can define the space of functions on \( G \) and endow it with the scalar product

\[
(f_1 | f_2) = \frac{1}{\text{ord} \, G} \sum_{g \in G} f_1^*(g) f_2(g) \tag{13}
\]

in order to make it a unitary space.

Suppose we have an irrep \( D^{(\alpha)} \) with dimension \( d_\alpha \). Then with respect to a basis the irrep consists of matrices and we can conceive the matrix elements \( D^{(\alpha)}_{ij}(g) \) as functions on \( G \). With Schur’s lemma (not to be confused with theorem 1 (Schur)) it is rather easy to prove the following theorem \([7, 8, 9]\).

**Theorem 6.** For irreps \( D^{(\alpha)} \) and \( D^{(\beta)} \) with dimensions \( d_\alpha \) and \( d_\beta \), respectively, the orthogonality relations

\[
\sum_{g \in G} D^{(\alpha)}_{ij}(g^{-1}) D^{(\beta)}_{kl}(g) = \frac{\text{ord} \, G}{d_\alpha} \delta_{\alpha \beta} \delta_{jk} \delta_{il} \tag{14}
\]

hold.

For finite groups we can always assume that the representation matrices are unitary. In this case \( D^{(\alpha)}_{ij}(g^{-1}) = (D^{(\alpha)\dagger})_{ij}(g) = (D^{(\alpha)}_{ji}(g))^\dagger \) is valid and equation (14) can be rewritten as

\[
(D^{(\alpha)}_{ji} | D^{(\beta)}_{kl}) = \frac{1}{d_\alpha} \delta_{\alpha \beta} \delta_{jk} \delta_{il}. \tag{15}
\]
The character of a representation:} For any representation $D$ its character is defined by the function

$$\chi : g \in G \rightarrow \chi(g) = \text{Tr} D(g) \in \mathbb{C},$$

(16)

where Tr denotes the trace. The character has the property that it is constant on every class $C_k$.

Let us move to the characters of irreps. We denote by $\chi^{(\alpha)}$ the character of the irrep $D^{(\alpha)}$. These characters have the following properties:

$$\chi^{(\alpha)}(e) = d_\alpha, \quad \sum_{g \in G} \left(\chi^{(\alpha)}(g)\right)^* \chi^{(\beta)}(g) = \delta_{\alpha\beta} \text{ord } G.$$  

(17)

The first relation is trivial, the second one follows from equation (14). If we denote by $c_k$ be the number of elements in class $C_k$ and by $\chi^{(\alpha)}_k$ the value of $\chi^{(\alpha)}$ on $C_k$, then the orthogonality relation for the characters of irreps reads

$$\sum_{k=1}^n c_k \left(\chi^{(\alpha)}_k\right)^* \chi^{(\beta)}_k = \delta_{\alpha\beta} \text{ord } G,$$

(18)

where $n$ is the number of classes.

**Character tables:** Since according to theorem \[\text{[1]}\] for every group $G$ the number of classes, $n$, equals the number of inequivalent irreps, one can depict a quadratic scheme of numbers $\chi^{(\alpha)}_k$, with columns and lines marked by $k$ and $\alpha$, respectively. Such a scheme is called character table of the group $G$—see table \[\text{[1]}\]. Note that this scheme is usually supplemented by two further lines as shown in table \[\text{[1]}\] for providing further information on the group. It is customary to set $C_1 = \{e\}$, thus in the first column the dimensions $d_\alpha = \chi^{(\alpha)}_1$ of the irreps can be read off. Furthermore, the usual convention is that $D^{(1)}$ is the trivial irrep, therefore, $\chi^{(1)}_k = 1 \forall k$. Moreover, the irreps are ordered according to increasing dimensions.

From equation (18) we know that the line vectors

$$\left(\sqrt{\frac{c_1}{\text{ord } G}} \chi^{(\alpha)}_1, \ldots, \sqrt{\frac{c_n}{\text{ord } G}} \chi^{(\alpha)}_n\right),$$

(19)

form an ON basis of $\mathbb{C}^n$. Consequently, also the column vectors

$$\sqrt{\frac{c_k}{\text{ord } G}} \begin{pmatrix} \chi^{(1)}_k \\ \vdots \\ \chi^{(n)}_k \end{pmatrix} \quad (k = 1, \ldots, n)$$

(20)
define an ON basis whose orthonormality conditions can be reformulated as

$$\sum_{\alpha=1}^{n} \left( \chi_{k}^{(\alpha)} \right)^{*} \chi_{\ell}^{(\alpha)} = \frac{\text{ord } G}{c_k} \delta_{k\ell}. \quad (21)$$

Equations (18) and (21) are useful for the construction of a character table.

**Reducible representations and character tables:** Suppose a representation $D$ of a group $G$ is given. Then with its character table it is straightforward to find its decomposition into irreps because the character of a reducible representation is a sum

$$\chi_{D} = \sum_{\alpha=1}^{n} n_{\alpha} \chi^{(\alpha)} \quad (22)$$

where the $n_{\alpha}$ denote the multiplicities with which the irreps $D^{(\alpha)}$ occur in $D$. Consequently,

$$n_{\alpha} = \left( \chi^{(\alpha)} | \chi_{D} \right). \quad (23)$$

This relation is particularly useful for tensor products because the character of the tensor product $D^{(\alpha)} \otimes D^{(\beta)}$ is given by the product of the characters of $D^{(\alpha)}$ and $D^{(\beta)}$:

$$\chi^{(\alpha \otimes \beta)}(g) = \chi^{(\alpha)}(g) \times \chi^{(\beta)}(g). \quad (24)$$
2.5 The group $S_4$

Let us examine the symmetric group $S_4$, i.e. the group of permutations of four objects, in the light of our group-theoretical discussion. We have chosen $S_4$ for two reasons. First, it is a group which is popular for model building—see e.g. [15] for a very early paper with $S_4$ used in the quark sector and two recent papers [16, 17] where this group is a symmetry in the lepton sector. Second, for the symmetric groups $S_n$ there is a general and simple rule how to find its classes.

The order of $S_n$ is $n!$. Every element $p \in S_n$ can be written as

$$p = \begin{pmatrix} 1 & 2 & \cdots & n \\ p_1 & p_2 & \cdots & p_n \end{pmatrix}.$$  \hspace{1cm} (25)

This scheme means that $i$ is mapped to $p_i$ ($i = 1, \ldots, n$). One can also present permutations as cycles. A cycle of length $r$ is a mapping

$$(n_1 \rightarrow n_2 \rightarrow n_3 \rightarrow \cdots \rightarrow n_r \rightarrow n_1) \equiv (n_1 n_2 n_3 \cdots n_r)$$  \hspace{1cm} (26)

such that all numbers $n_1, \ldots, n_r$ are different. Evidently, every permutation is a unique product of cycles which have no common elements. For instance,

$$\begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 4 & 6 & 3 & 5 & 1 & 2 \end{pmatrix} = (145)(3)(26).$$  \hspace{1cm} (27)

Cycles which have no common element commute and a cycle which consists of only one element is identical with the unit element of $S_n$. The classes of $S_n$ are characterized by the cycle structure [7].

**Theorem 7.** The classes of $S_n$ consist of the permutations with the same cycle structure.

Let us apply this to $S_4$. The theorem says that it has five classes corresponding to the cycle structures $e$, $(n_1 n_2)$, $(n_1 n_2)(n_3 n_4)$, $(n_1 n_2 n_3)$ and $(n_1 n_2 n_3 n_4)$. Its corresponding classes will be denoted by $C_1, \ldots, C_5$, respectively, in the following. Thus, $S_4$ has five inequivalent irreps.

There is another useful theorem concerning $S_n$.

**Theorem 8.** $S_n$ has exactly two 1-dimensional irreps: $p \rightarrow 1$ and $p \rightarrow \text{sgn}(p)$.\footnote{In general, the problem of finding the classes of a group can be quite tricky, if its order is large.}

11
The sign of a permutation is $+1$ ($-1$), if it can be decomposed into an even (odd) number of transpositions, i.e. cycles of length $r = 2$. A cycle of length $r$ is even (odd) if $r$ is odd (even).

Now we can easily find the dimensions of all irreps of $S_4$. We know already that there are five irreps, with two of them having dimension one. Thus, according to theorem [4], we have the equation $1^2 + 1^2 + d_3^2 + d_4^2 + d_5^2 = 24$. One can easily check that the solution is unique (up to reordering): $d_3 = 2$, $d_4 = d_5 = 3$.

In order to find the remaining three irreps we take advantage of the fact that Klein’s four-group

$$K = \{ e, (12)(34), (13)(24), (14)(23) \} \cong \mathbb{Z}_2 \times \mathbb{Z}_2$$

(28)

is a normal, abelian subgroup of $S_4$. That it is an abelian subgroup is easily checked, that $K$ is also normal follows from theorem [4]. We observe that $S_3$ can be conceived as subgroup of $S_4$ if we consider the permutations of only 2, 3, 4. One can check that $K$ and the $S_3$ defined in this way have exactly the properties of $H$ and $G$ of theorem [2]. Therefore,

$$S_4 \cong K \rtimes S_3$$

(29)

and every element of $S_4$ can uniquely be decomposed into $s = kp$ with $k \in K$ and $p \in S_3$.

Taking advantage of equation (29), we find the 2-dimensional irrep as

$$kp \rightarrow D_2(p) \quad \text{with} \quad D_2((234)) = \begin{pmatrix} \omega & 0 \\ 0 & \omega^2 \end{pmatrix}, \quad D_2((34)) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. $$

(30)

Note that $D_2$ is an irrep of $S_3$. Clearly, $K$, which is represented trivially as we have discussed in section [2.1], and the two cycles in equation (30) generate the full $S_4$, thus we really have found the complete 2-dimensional irrep.

It remains to construct the two 3-dimensional irreps. We only sketch the procedure. A 3-dimensional representation of $K \cong \mathbb{Z}_2 \times \mathbb{Z}_2$ is given by

$$
(12)(34) \rightarrow \text{diag} \begin{pmatrix} 1, -1, -1 \end{pmatrix}, \\
(13)(24) \rightarrow \text{diag} \begin{pmatrix} -1, 1, -1 \end{pmatrix}, \\
(14)(23) \rightarrow \text{diag} \begin{pmatrix} -1, -1, 1 \end{pmatrix}.
$$

(31)
We denote the representation of $K$ by $A(k)$. Obviously, the mapping
\[
(34) \rightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad (24) \rightarrow \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad (23) \rightarrow \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}
\]

(32)
generates a representation of the $S_3$ which permutes the numbers 2, 3, 4. We denote this representation by $M_3(p)$. It is not difficult to check that $kp \rightarrow A(k)M_3(p)$ is indeed a representation of $S_4$. Obviously, it is irreducible. The second 3-dimensional irrep is obtained by multiplication of the previous one with $\text{sgn}(p)$.

Thus we have the following summary of the $S_4$ irreps:

\[
s = kp \in S_4 \Rightarrow \begin{array}{l}
1 : \ kp \rightarrow 1, \\
1' : \ kp \rightarrow \text{sgn}(p), \\
2 : \ kp \rightarrow D_3(p), \\
3 : \ kp \rightarrow A(k)M_3(p), \\
3' : \ kp \rightarrow \text{sgn}(p) A(k)M_3(p).
\end{array}
\]

Note that $\text{sgn}(kp) = \text{sgn}(p) = \det M_3(p)$.

Having all classes and irreps at our disposal, we can write down character table 2. As an application we compute the decomposition of $3 \otimes 3$ into irreps. The character of $3 \otimes 3$ is given by the square of the line labeled by $3$ in table 2:

\[
\chi^{3 \otimes 3} = [9 \ 1 \ 1 \ 0 \ 1].
\]

With equation (23) the multiplicities of the irreps in $3 \otimes 3$ are computed. The whole information for this computation is contained in the character

Table 2: Character table of $S_4$. 

13
All products of three numbers in this computation are given by

\[ c_k \times \chi_k^{(a)} \times \chi_k^{3\odot3} \]

Thus the result of the decomposition is

\[ 3 \odot 3 = 1 \oplus 2 \oplus 3 \oplus 3' \]  \hspace{1cm} (35)

With some experience it is not difficult to guess the Clebsch–Gordan coefficients—for their definition see e.g. \cite{[7, 8]}. Denoting the cartesian basis vectors in 3 by \( e_j \) \((j = 1, 2, 3)\) and defining \( \omega = e^{2\pi i/3} \) we find

\[ \begin{align*}
1 & : \frac{1}{\sqrt{3}} (e_1 \otimes e_1 + e_2 \otimes e_2 + e_3 \otimes e_3), \\
2 & : \begin{cases}
\frac{1}{\sqrt{3}} (e_1 \otimes e_1 + \omega^2 e_2 \otimes e_2 + \omega e_3 \otimes e_3), \\
\frac{1}{\sqrt{3}} (e_1 \otimes e_1 + \omega e_2 \otimes e_2 + \omega^2 e_3 \otimes e_3),
\end{cases} \\
3 & : \begin{cases}
\frac{1}{\sqrt{2}} (e_2 \otimes e_3 + e_3 \otimes e_2), \\
\frac{1}{\sqrt{2}} (e_3 \otimes e_1 + e_1 \otimes e_3), \\
\frac{1}{\sqrt{2}} (e_1 \otimes e_2 + e_2 \otimes e_1), \\
\frac{1}{\sqrt{2}} (e_2 \otimes e_3 - e_3 \otimes e_2), \\
\frac{1}{\sqrt{2}} (e_1 \otimes e_2 - e_2 \otimes e_1).
\end{cases} \\
3' & : \begin{cases}
\frac{1}{\sqrt{2}} (e_3 \otimes e_1 - e_1 \otimes e_3), \\
\frac{1}{\sqrt{2}} (e_1 \otimes e_2 - e_2 \otimes e_1).
\end{cases}
\end{align*} \]  \hspace{1cm} (36)

### 2.6 The group \( A_4 \)

After the seminal paper by Ma and Rajasekaran \cite{[18]}, this group has become the most popular one in the context of neutrino masses and lepton mixing. We can only list a few early papers here in \cite{[19, 20]}, refer the reader to the
review [6] and to citations in recent $A_4$ papers to get an impression of the bustling activities with respect to model building with $A_4$. It is worth noting that this group has already been used much earlier in the quark sector [21].

The group $A_4$ consists of all even permutations of $S_4$. Therefore, its structure is

$$A_4 \cong K \rtimes \mathbb{Z}_3.$$  \hfill (37)

Theorem 7 cannot be applied to find the classes, it is however clear that the classes of $A_4$ must be subsets of the classes of $S_4$ which consist of even permutations. In this way we obtain

$$
\begin{align*}
C_1 &= \{e\}, \\
C_2 &= \{(12)(34), (13)(24), (14)(23)\}, \\
C_3 &= \{(132), (124), (234), (143)\}, \\
C_4 &= \{(123), (142), (243), (134)\}.
\end{align*}
$$  \hfill (38)

Thus we know that $A_4$ has four inequivalent irreps. Equation (37) tells us that there are three 1-dimensional irreps stemming from the $\mathbb{Z}_3$, which map $K$ onto 1:

$$
\begin{align*}
1 : (243) &\rightarrow 1, \\
1' : (243) &\rightarrow \omega^2, \\
1'' : (243) &\rightarrow \omega.
\end{align*}
$$  \hfill (39)

Since $A_4$ has 12 elements, the remaining irrep must have dimension three. Equations (31) and (32) for $S_4$ allow to determine this irrep:

$$
(12)(34) \rightarrow A \equiv \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad (243) \rightarrow E = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}.
$$  \hfill (40)

For the second relation we have exploited the relation $(243) = (23)(24)$. An alternative definition of $A_4$ is given by this irrep because the $3$ is faithful. In this way, $A_4$ can be considered as a finite subgroup of $SU(3)$ with generators $A$ and $E$.

Having constructed all irreps we can write down the character table of $A_4$—see table 3. As an example for its usage one can, for instance, compute

$$3 \otimes 3 = 1 \oplus 1' \oplus 1'' \oplus 3 \oplus 3.$$  \hfill (41)

The Clebsch–Gordan decomposition of this tensor product is given by

$$
\begin{align*}
1 : & \frac{1}{\sqrt{3}} \left( e_1 \otimes e_1 + e_2 \otimes e_2 + e_3 \otimes e_3 \right), \\
1' : & \frac{1}{\sqrt{3}} \left( e_1 \otimes e_1 + \omega^2 e_2 \otimes e_2 + \omega e_3 \otimes e_3 \right), \\
1'' : & \frac{1}{\sqrt{3}} \left( e_1 \otimes e_1 + \omega e_2 \otimes e_2 + \omega^2 e_3 \otimes e_3 \right), \\
3 : & e_2 \otimes e_3, e_3 \otimes e_1, e_1 \otimes e_2, \\
3 : & e_3 \otimes e_2, e_1 \otimes e_3, e_2 \otimes e_1.
\end{align*}
$$  \hfill (42)
For the two 3-dimensional irreps one could equivalently use the symmetric and antisymmetric combinations of $e_j \otimes e_k$, or any other weighted, orthogonal combination. Note that for $S_4$ one does not have this freedom, one must use the symmetric combination for the $3$ and the antisymmetric combination for the $3'$—see equation (36). In the case of $A_4$ this freedom comes about because the $3'$ becomes identical with the $3$ due to the absence of transpositions.

### 3 Models of neutrino masses and lepton mixing

#### 3.1 Lagrangians and horizontal symmetries

We begin with some remarks. The notion “horizontal symmetry” is used synonymously with “family symmetry”:

- We assume that any model we have in mind is an extension of the Standard Model. Therefore, the full symmetry group of the Lagrangian $\mathcal{L}$ is $G_{\text{gauge}} \times G_{\text{family}}$. ($G_{\text{family}}$ could also be gauged, but we do not consider this possibility here.)

- Kinetic and gauge terms in the Lagrangian are automatically invariant under $G_{\text{family}}$.

- Therefore, the effect of $G_{\text{family}}$ is felt in the Yukawa Lagrangian and the scalar potential.

- The Yukawa couplings are connected with the Clebsch–Gordan coefficients of the tensor products of the fermion representations, such that

for every irrep of scalar fields there is a free Yukawa coupling constant.

- The mass matrices contain, in addition, the vacuum expectation values (VEVs) which are determined by the minimum of the scalar potential.

- With several VEVs one has the problem of vacuum alignment. The meaning of this notion is that only specific VEV relations lead to mass matrices which give the desired mixing angles and, sometimes in addition, predictions for the neutrino mass spectrum.

- With family symmetries one has almost necessarily a proliferation of the scalar sector and, in most cases, also additional fermion fields. Thus there is a tension between the introduction of new fields and, as a consequence, unknown constants, which are necessary to realize the symmetry, and the attempted predictions for masses and mixings.

Let us discuss the relation between Clebsch–Gordan coefficients and Yukawa couplings in more detail. Suppose we have a tensor product \( D \otimes D' = D_S \oplus \cdots \) with irreps \( D, D' \) and \( D_S \). We choose the bases \( D : \{e_\alpha\} \) and \( D' : \{f_\alpha\} \). Then the basis for irrep \( D_S \) has the form \( \{b_i = \Gamma_{i\alpha\beta} e_\alpha \otimes f_\beta\} \).

With the transformations

\[
e_\alpha \rightarrow D_{\gamma\alpha}e_\gamma, \quad f_\beta \rightarrow D_{\delta\beta}f_\delta, \quad b_i \rightarrow (D_S)_{ji}b_j
\]

the conditions on the Clebsch–Gordan coefficient matrices \( \Gamma_i \) are obtained as

\[
\Gamma_i = (D^\dagger \Gamma J D'')(D_S)_{ji}.
\]

Now we consider generic Yukawa couplings in the Majorana form

\[
L_Y = y_s \psi^T C^{-1} \gamma_{i\alpha\beta} S_i \psi'_\beta + \text{H.c.},
\]

where \( \psi \) and \( \psi' \) transform according to \( D \) and \( D' \), respectively. Comparing with equation (44) we find that

\[
\psi \rightarrow D \psi, \quad D' \rightarrow D' \psi' \quad \Rightarrow \quad S \rightarrow D^*_S S, \quad \gamma_i = \Gamma_i^*.
\]

I.e., the scalar fields transform with the irrep complex conjugate to \( D_S \) and the Yukawa couplings are partially determined by the complex conjugate Clebsch–Gordan coefficient matrix, as announced above.

If we have three fermion families then the fermion multiplets constitute 3-dimensional representations of the horizontal group \( G \). We can distinguish three cases:
i. Abelian case: Only 1-dimensional irreps are present.

ii. Non-Abelian case: 2-dimensional irreps occur, but no 3-dimensional one.

iii. Non-Abelian case: 3-dimensional irreps occur.

An Abelian group $G$ is synonymous with “texture zeros”, i.e., a Yukawa coupling is either present and undetermined or it is zero, but there are no relations between different Yukawa couplings. Relations among observables in the mass spectrum and mixing have their origin solely in these zeros. It has been shown [22] that by Abelian symmetries the only extremal mixing angle which can be enforced is $\theta_{13} = 0^\circ$. It is possible to enforce texture zeros in arbitrary entries of the fermion mass matrices by means of Abelian symmetries and an extended scalar sector [23].

In the second case it is possible to enforce $\theta_{13} = 0^\circ$ and $\theta_{23} = 45^\circ$. For tri-bimaximal mixing one needs 3-dimensional irreps. In the next subsection we will discuss one such model based on $A_4$.

### 3.2 A type I seesaw model based on $A_4$

As a prototype for a renormalizable $A_4$ model we discuss the model of [20]. It is based on the following $A_4$ multiplets:

\begin{align}
\text{fermion fields: } & \ell_R \in 1 \oplus 1' \oplus 1'', \quad D_L \in 3, \quad \nu_R \in 3, \\
\text{scalar fields: } & \phi \in 3, \quad \phi_0 \in 1, \quad \chi \in 3. \quad (47)
\end{align}

In this list the $D_L$ are the usual leptonic left-handed gauge doublets, the $\ell_R$ are the right-handed charged gauge singlets and the $\nu_R$ are the right-handed neutrino singlets. There are four Higgs doublets $\phi$ and $\phi_0$ with hypercharge +1 and three real gauge singlets $\chi$.

With the discussion in the previous section it is straightforward to derive the Lagrangian

\begin{align}
\mathcal{L} = & - \left[ h_1 \left( \bar{D}_{1L} \phi_1 + \bar{D}_{2L} \phi_2 + \bar{D}_{3L} \phi_3 \right) \ell_1 R \\
& + h_2 \left( \bar{D}_{1L} \phi_1 + \omega^2 \bar{D}_{2L} \phi_2 + \omega \bar{D}_{3L} \phi_3 \right) \ell_2 R \\
& + h_3 \left( \bar{D}_{1L} \phi_1 + \omega \bar{D}_{2L} \phi_2 + \omega^2 \bar{D}_{3L} \phi_3 \right) \ell_3 R \\
& + h_0 \left( \bar{D}_{1L} \nu_{1R} + \bar{D}_{2L} \nu_{2R} + \bar{D}_{3L} \nu_{3R} \right) \tilde{\phi}_0 + \text{H.c.} \right] \quad (48) \\
& + \frac{1}{2} \left[ M \left( \nu_{1R} C^{-1} \nu_{1R} + \nu_{2R} C^{-1} \nu_{2R} + \nu_{3R} C^{-1} \nu_{3R} \right) + \text{H.c.} \right] \quad (49)
\end{align}
\[ + \frac{1}{2} \left[ \chi_1 \left( \nu_{2R}^T C^{-1} \nu_{3R} + \nu_{3R}^T C^{-1} \nu_{2R} \right) \\
+ \chi_2 \left( \nu_{3R}^T C^{-1} \nu_{1R} + \nu_{1R}^T C^{-1} \nu_{3R} \right) \\
+ \chi_3 \left( \nu_{1R}^T C^{-1} \nu_{2R} + \nu_{2R}^T C^{-1} \nu_{1R} \right) \right] + \text{H.c.} \], \quad (51)

where we have confined ourselves to the Yukawa interactions and mass terms. The dots indicate the kinetic terms, the gauge interactions and the scalar potential.

Through spontaneous symmetry breaking with VEVs \( v_j, w_j \) \((j = 1, 2, 3)\) and \( v_0 \) of the Higgs doublets and scalar singlets, respectively, the Lagrangian leads to the mass terms

\[- \bar{\ell}_L M_\ell \ell_R - \bar{\nu}_L M_D \nu_R + \frac{1}{2} \nu_R^T C^{-1} M_R \nu_R + \text{H.c.} \quad (52)\]

While \( M_D = h_0 v_0^* \mathbb{1} \) is simply proportional to the unit matrix, the other two mass matrices are given by

\[
M_\ell = \begin{pmatrix}
  h_1 v_1 & h_2 v_1 & h_3 v_1 \\
  h_1 v_2 & h_2 v_2 \omega^2 & h_3 v_2 \omega \\
  h_1 v_3 & h_2 v_3 \omega & h_3 v_3 \omega^2
\end{pmatrix} \quad \text{and} \quad M_R = \begin{pmatrix}
  M & h_\chi w_3 & h_\chi w_2 \\
  h_\chi w_3 & M & h_\chi w_1 \\
  h_\chi w_2 & h_\chi w_1 & M
\end{pmatrix}. \quad (53)
\]

With general VEVs one cannot obtain tri-bimaximal mixing. It is well known that the vacuum alignment

\[
v_1 = v_2 = v_3 \equiv v, \quad w_1 = w_3 = 0, \quad h_\chi w_2 \equiv M'
\]

is needed, which gives the mass matrices

\[
M_\ell = \sqrt{3} v U_\omega \begin{pmatrix}
  h_1 & 0 & 0 \\
  0 & h_2 & 0 \\
  0 & 0 & h_3
\end{pmatrix}, \quad M_R = \begin{pmatrix}
  M & 0 & M' \\
  0 & M & 0 \\
  M' & 0 & M
\end{pmatrix}. \quad (55)
\]

The matrix \( U_\omega \) can be read off from \( M_\ell \) in equation (53). We denote by \( U_\nu \) the matrix which diagonalizes \( M_R \) of equation (55). These two unitary matrices are then obtained as

\[
U_\omega = \frac{1}{\sqrt{3}} \begin{pmatrix}
  1 & 1 & 1 \\
  1 & \omega & \omega^2 \\
  1 & \omega^2 & \omega
\end{pmatrix}, \quad U_\nu = \begin{pmatrix}
  1/\sqrt{2} & 0 & -1/\sqrt{2} \\
  0 & 1 & 0 \\
  1/\sqrt{2} & 0 & 1/\sqrt{2}
\end{pmatrix}. \quad (56)
\]

Therefore, up to diagonal phase matrices on the left and right-hand side, we arrive at the lepton mixing matrix

\[
U = U_\omega U_\nu = \text{diag} (1, \omega, \omega^2) U_{\text{HPS}} \text{diag} (1, 1, -i). \quad (57)
\]
Thus the $A_4$ symmetry of the Lagrangian together with suitable vacuum alignment leads to tri-bimaximal mixing. The charged-lepton masses are reproduced by choosing the Yukawa couplings appropriately: $m_\alpha = \sqrt{3}|v h_\alpha|$ ($\alpha = e, \mu, \tau$).

We conclude the discussion of the model of [20] with a few comments. As shown above, vacuum alignment is a very important ingredient for achieving tri-bimaximal mixing. Of course, the symmetry group also restricts the scalar potential and is essential for allowing the required vacuum structure to be a minimum of the scalar potential. Nevertheless, vacuum alignment is usually a tricky problem. In the model we have discussed it was necessary to break $A_4$ down to $\mathbb{Z}_3$ generated by the matrix $E$—see equation (40)—in the charged lepton sector, while in the neutrino sector the VEVs of the scalars $\chi_k$ break $A_4$ to a $\mathbb{Z}_2$ generated by $\text{diag}(-1, 1, -1)$. This is quite generic for $A_4$ models with tri-bimaximal mixing and leads to $M_D \propto \mathbb{1}$ and the structure of $M_\ell$ and $M_R$ of equation (55). It was shown in [20] that the vacuum alignment (54) is possible if the scalar potential is CP-conserving. Since in this model $\ell_R$ is not in the same $A_4$ multiplet as $D_L$ and $\nu_R$, it cannot be embedded in a Grand Unified Theory. Note, however, that it is possible to put both $D_L$ and $\ell_R$ into a $3$ and to use the type II seesaw mechanism with scalar gauge triplets—see for instance [24], a scenario which can at least in principle be extended to a Grand Unified Theory.

4 Conclusions

A large part of this lecture dealt with the theory of finite groups, the other part with the application of group theory to Lagrangians for the purpose of “explaining” mass and mixing patterns found experimentally or to make predictions in this context. Let us finish with remarks on the second part.

We have tried to demonstrate that symmetries based on finite groups could be a way to tackle the mass and mixing problem. However, all models for lepton mixing (and neutrino masses) require complicated and contrived extensions of the Standard Model. Such models are in most cases incompatible with Grand Unification, need vacuum alignment, employ SUSY and non-renormalizable terms, etc. Here we have confined ourselves to the relatively simple renormalizable model of [20] as a showcase, which manages without SUSY. As for tri-bimaximal mixing (2), for the time being it is compatible with all experimental results. However, it could turn out that $s_{13}^2 \sim 0.01$ [3]. In that case, ideas alternative to tri-bimaximal mixing would
be in demand. Or one assumes that tri-bimaximal mixing holds at a high (seesaw) scale and, by the renormalization group evolution of the mixing angles from the high scale down to the electroweak scale, $s_{13}^2$ evolves sufficiently away from zero; this is possible with a degenerate neutrino mass spectrum.

Acknowledgments: The author thanks the organizers for their kind hospitality and the pleasant atmosphere at the school. Furthermore, he is very grateful to Patrick Ludl for a careful reading of the manuscript.
