Abstract

We present a measurement of the ratio $\sigma \cdot B(W \rightarrow e\nu)/\sigma \cdot B(Z^0 \rightarrow e^+e^-)$ in $\bar{p}p$ collisions at $\sqrt{s} = 1.8 \text{ TeV}$. The data represent an integrated luminosity of 21.7 pb^{-1} from the 1992-1993 run of the Collider Detector at Fermilab. We find $\sigma B(W \rightarrow e\nu)/\sigma B(Z^0 \rightarrow e^+e^-) = 10.90 \pm 0.32(\text{stat.}) \pm 0.29(\text{sys.})$. From this value, we extract a value for the W width, $\Gamma(W) = 2.063 \pm 0.061(\text{stat.}) \pm 0.060(\text{sys.}) \text{ GeV}$, and the branching ratio, $\Gamma(W \rightarrow e\nu)/\Gamma(W) = 0.1094 \pm 0.0033(\text{stat.}) \pm 0.0031(\text{sys.})$, and we set a decay mode independent limit on the top quark mass, $m_{\text{top}} > 62 \text{ GeV}/c^2$ at the 95% C.L.

The ratio of the production cross sections times the branching ratios into electrons of W and Z^0 bosons produced in $\bar{p}p$ collisions is related[1] to the W decay width, $\Gamma(W)$, by

$$R \equiv \frac{\sigma B(W \rightarrow e\nu)}{\sigma B(Z^0 \rightarrow e^+e^-)} = \frac{\sigma(\bar{p}p \rightarrow WX)}{\sigma(\bar{p}p \rightarrow Z^0X)} \frac{\Gamma(W \rightarrow e\nu)}{\Gamma(Z^0 \rightarrow e^+e^-)} \frac{\Gamma(Z^0)}{\Gamma(W)}, \quad (1)$$

where $\sigma(\bar{p}p \rightarrow WX)/\sigma(\bar{p}p \rightarrow Z^0X)$ is the ratio of the production cross sections of W 's and Z^0 's in $\bar{p}p$ collisions, $\Gamma(W \rightarrow e\nu)$ is the W partial width to an electron and neutrino, $\Gamma(Z^0 \rightarrow e^+e^-)$ is the Z^0 partial width into electrons, and $\Gamma(W)$ and $\Gamma(Z^0)$ are the W and Z^0 total decay widths. The ratio of the production cross sections can be calculated using the Standard Model couplings and parton distribution functions, as can the ratio of partial decay widths. With the LEP[2] measurements of $\Gamma(Z^0)$ and $\Gamma(Z^0 \rightarrow e^+e^-)$, one can extract a value for the branching ratio $\Gamma(W \rightarrow e\nu)/\Gamma(W)$ from a measurement of R . Alternatively, one may use a calculation of $\Gamma(W \rightarrow e\nu)/\Gamma(Z^0 \rightarrow e^+e^-)$ and the LEP value for $\Gamma(Z^0)$ to extract a value for the W decay width, $\Gamma(W)$.

Many theoretical and experimental systematic uncertainties cancel in measuring the ratio, making this the most precise method at present for determining the branching ratio $\Gamma(W \rightarrow e\nu)/\Gamma(W)$. An accurate determination of $\Gamma(W \rightarrow e\nu)/\Gamma(W)$ is sensitive to decay channels of the W outside the Standard Model. Previous measurements of R at $\sqrt{s} = 1.8 \text{ TeV}$ [3, 4] and at $\sqrt{s} = 0.63 \text{ TeV}$ [5, 6] have yielded a combined accuracy on the W width of 5.2%.

We present results using 21.7 pb^{-1} of data from proton-antiproton collisions at a center of mass energy of $\sqrt{s} = 1.8 \text{ TeV}$ collected at the Collider Detector at Fermilab (CDF) during the 1992-1993 run of the Fermilab Tevatron. The CDF Detector is described in detail elsewhere[7]. The components of the detector relevant for this analysis are (i) two scintillator hodoscopes located on either side of the detector, (ii) the Silicon Vertex Detector (SVX)[8], (iii) the time-projection chamber (VTX), (iv) a drift chamber (CTC) immersed in a 1.4 T solenoidal magnetic field, and (v) electromagnetic and hadronic calorimeters. The

calorimeters are arranged in projective towers and cover the pseudorapidity ranges $|\eta| < 1.05$ (Central calorimeters), $1.1 < |\eta| < 2.4$ (Plug calorimeters), and $2.4 < |\eta| < 4.2$ (Forward calorimeters). In the Central electromagnetic calorimeters, proportional chambers are embedded near shower maximum for fine position measurement. A pre-shower detector (CPR) is located on the inner face of the Central calorimeter.

We select W and Z^0 candidates from a common set of inclusive electrons with transverse energy $E_T > 20 \text{ GeV}$ in the Central region.[9] We also require that the event was triggered by the Central electron[10]. Requiring both W 's and Z^0 's to pass this requirement reduces systematic uncertainties in the selection efficiencies when taking the ratio. Placing tight selection criteria on this first, Central electron also allows us to place loose, highly efficient selection criteria on the second lepton (either ν or e). The selection criteria for electrons at CDF can be found in Ref [10]. These selection criteria include an isolation (Iso) cut[11] on the amount of energy in the calorimeter near the electron cluster.

The Z^0 candidates are selected from the inclusive electron sample by requiring a second electron and an invariant mass of the electron pair in the mass range $66 - 116 \text{ GeV}/c^2$. The second electron is required to have $E_T > 20 \text{ GeV}$ if in the Central, $E_T > 15 \text{ GeV}$ if in the Plug, or $E_T > 10 \text{ GeV}$ if in the Forward. Other selection criteria are as listed in[10]. Figure 1(a) shows the invariant mass spectrum of all electron pairs satisfying our electron criteria; of these, 1312 in the mass range $66 - 116 \text{ GeV}/c^2$ are Z^0 candidates.

W candidates are selected from the inclusive electron sample by requiring that the event is not a Z^0 candidate and that the event has a transverse energy imbalance ($\cancel{E}_T \equiv \text{“missing } E_T\text{”}$) of $\cancel{E}_T > 20 \text{ GeV}$, where $\cancel{E}_T$ is the magnitude of the vector sum of all calorimeter tower transverse energies using towers with $|\eta| < 3.6$. Figure 1(b) shows the transverse mass spectrum of the 13796 W candidates, where $M_T \equiv \sqrt{2E_T^{e\bar{e}}\cancel{E}_T(1 - \cos(\Delta\phi))}$, and $\Delta\phi$ is the azimuthal angle between the electron and the $\cancel{E}_T$ vector.

The dominant background to the W candidates comes from hadron jets, where one jet produces an isolated high- P_T electron and the other jet is mismeasured in the calorimeters, creating $\cancel{E}_T$. The jet

fragmentations which produce isolated[11], high- P_T clusters which pass our electron criteria are photon conversions to e^+e^- pairs in the material within the tracking volume, semileptonic decays of heavy quarks, $b \rightarrow ce\nu$, and hadrons which shower early in the calorimeter. We estimate the sum of these backgrounds by comparing the number of events in three background-dominated regions, ($\cancel{E}_T < 10 \text{ GeV}$, $Iso > 0.3$), ($\cancel{E}_T < 10 \text{ GeV}$, $Iso < 0.1$), ($\cancel{E}_T > 20 \text{ GeV}$, $Iso > 0.3$), and using the ratios to extrapolate into the signal region ($\cancel{E}_T > 20 \text{ GeV}$, $Iso < 0.1$). We calculate the number of hadron jet events with an electron and $\cancel{E}_T > 20 \text{ GeV}$ to be 2100 ± 350 events, and the number to contaminate the W region with $Iso < 0.1$ to be 898 ± 155 events, where the estimated uncertainties are based on studies of correlations of these variables with jet energies. As a check of this method, the backgrounds from conversions, semileptonic b decays, and hadron showers are studied separately. Conversions are identified by searching for oppositely-signed charged tracks in the tracking chamber near the electron for which the pair forms a small invariant mass. Semileptonic b decays can be identified statistically using the SVX to search for electrons that come from a displaced vertex. Hadrons showering early in the calorimeter were identified by a minimum ionizing pulse in the CPR. From these studies, we estimate the number of conversions at $\cancel{E}_T > 20 \text{ GeV}$ to be 910 ± 80 , the number of electrons from b decays to be 850 ± 360 , and the number of fake electrons from hadron showers to be 580 ± 370 , which add up to 2340 ± 520 , consistent with the 2100 ± 350 events above.

Other backgrounds to the W come from $W^\pm \rightarrow \tau^\pm \nu \rightarrow e^\pm \nu \nu \nu$, from $Z^0 \rightarrow \tau^+ \tau^-$, where one τ decays to an e , from $Z^0 \rightarrow e^+ e^-$ where one e is lost, and possibly from heavy top quark decays. We estimate all of these backgrounds using the ISAJET[12] Monte Carlo and a detector simulation. The upper limit on the top background comes from the expected number of events if $m_{top} = 120 \text{ GeV}/c^2$, which is the 68% C.L. limit from CDF[13]. Figure 1(b) shows the expected shape for the transverse mass of the W candidates when the background shapes are added to the expected signal shape. The W backgrounds are summarized in Table 1.

The dominant background to Z^0 candidates also comes from hadron jets that fluctuate to pass our Z^0 selection criteria. This background is estimated by a similar study of the Isolation variable[10] to that of the W 's to be 20 ± 9 events. The other background is from the process $Z^0 \rightarrow \tau^+ \tau^-$, where the τ 's decay into electrons. We estimate this background using ISAJET plus a detector simulation to be 1 ± 1 event. A correction of $0.5 \pm 0.2\%$ was applied to the number of Z^0 candidates to account for the e^+e^- pairs produced by the Drell-Yan γ continuum and not from resonant Z^0 production.

In terms of experimentally measured quantities, the ratio R is

$$R = \frac{N_W}{N_Z} \frac{A_Z}{A_W} \frac{\epsilon_Z}{\epsilon_W}, \quad (2)$$

where N_W is the number of W candidates after background subtraction, A_W is the geometric and kinematic acceptance for W decays, and ϵ_W is the lepton selection efficiency for the W , and similarly for the Z^0 's.

The ratio of efficiencies in Equation 2 is

$$\frac{\epsilon_Z}{\epsilon_W} = \frac{F_{cc}c_1(2c_2 - c_1) + F_{cp}c_1p + F_{cf}c_1f}{c_1}, \quad (3)$$

where c_1 is the efficiency for the Central electron to pass our inclusive electron selection (including the trigger efficiency), and c_2 , p , and f are the efficiencies for the second Z^0 electrons in Central, Plug, and Forward regions. F_{cc} , F_{cp} , and F_{cf} are the fractions of the Z^0 's in which the second electron falls in the Central, Plug, and Forward regions. The efficiency c_1 cancels almost completely in the ratio. The selection efficiencies are determined from the second electrons in a sample of Z^0 candidates where no cuts are imposed on the second electron. The ratio of efficiencies is determined to be $\epsilon_W/\epsilon_Z = 1.035 \pm 0.016$ (see Table 1).

The fractions F_{cc} , F_{cp} , and F_{cf} and the acceptances A_W and A_Z are determined from a Monte Carlo which generates bosons from the lowest order diagram, $q\bar{q} \rightarrow W$ or Z^0 , using various parton distribution

functions. The bosons are given a P_T according to the distribution measured previously by CDF[14]. The electron and neutrino energies are smeared with the calorimeter energy resolutions. The fiducial and kinematic cuts are then placed on the leptons. Using the MRS D-' parton distribution functions[15] and the world averages[2] for the electroweak parameters, we obtain $A_W/A_Z = 0.835$. Using other current parton distribution functions varies A_W/A_Z by 1.1%. Variations in the input P_T distribution lead to 0.2% variation in A_W/A_Z . Variations of $M_W = 80.24 \pm 0.10 \text{ GeV}/c^2$ within its uncertainty leads to a 0.1% variation in A_W/A_Z . The uncertainty in the modelling of the detector response to $\cancel{E}_T$ leads to a 0.6% uncertainty in A_W/A_Z . The uncertainty in the energy scale of the calorimeter leads to 0.4% variations in A_W/A_Z . Finally, from a comparison with a next-to-leading order calculation[16] of W and Z^0 production, we estimate the systematic uncertainty on using only the lowest-order matrix element plus the boson P_T to model higher-order diagrams to be 0.8%. The overall systematic uncertainty in A_W/A_Z is taken to be the sum of the above variations, namely $\pm 1.6\%$.

The results for R are summarized in Table 1. We find

$$R = 10.90 \pm 0.32(stat.) \pm 0.29(sys.). \quad (4)$$

Using the theoretical calculation[17] $\sigma(\bar{p}p \rightarrow WX)/\sigma(\bar{p}p \rightarrow Z^0X) = 3.33 \pm 0.03$, the calculation[18] $\Gamma(W \rightarrow e\nu)/\Gamma(Z^0 \rightarrow e^+e^-) = 2.710 \pm 0.018$, and the LEP measurement[2] $\Gamma(Z^0) = 2.492 \pm 0.007 \text{ GeV}$, and assuming Standard Model couplings to the fermions, we extract a value for the W width of

$$\Gamma(W) = 2.063 \pm 0.061(stat.) \pm 0.060(sys.) \text{ GeV}. \quad (5)$$

This is a 4.1% measurement of the W width. For comparison, the Standard Model prediction[19] is $2.067 \pm 0.021 \text{ GeV}$.

If we use the LEP value[2] for $\Gamma(Z^0 \rightarrow e^+e^-) = 83.33 \pm 0.30 \text{ MeV}$ instead of the theoretical calculation

of $\Gamma(W \rightarrow e\nu)/\Gamma(Z^0 \rightarrow e^+e^-)$, we can extract an absolute measure of the W branching ratio into $e\nu$:

$$\frac{\Gamma(W \rightarrow e\nu)}{\Gamma(W)} = 0.1094 \pm 0.0033(stat.) \pm 0.0031(sys.). \quad (6)$$

This measurement of the branching ratio is sensitive to new decay modes of the W . One such decay mode would be $W \rightarrow t\bar{b}$. While CDF[13] has set a limit on the top quark mass of $m_{top} > 91 \text{ GeV}/c^2$ (95% C.L.), this limit assumes Standard Model decays of the top quark. If, however, the top should decay in a manner outside the Standard Model, for example via charged Higgs ($t \rightarrow H^+b$), then the assumptions that go into previous direct searches are no longer valid.[20] The present result sets a limit on the top quark mass independent of presumed top decay channels. Figure 2 shows the Standard Model expectation for $\Gamma(W)/\Gamma(W \rightarrow e\nu)$ as a function of the top quark mass, m_{top} , along with our result. Using the prediction and this measurement, we set a decay mode independent limit[21] on the top quark mass of $m_{top} > 62 \text{ GeV}/c^2$ (95% C.L.).

We thank the Fermilab staff and the technical staffs of the participating institutions for their vital contributions. This work was supported by the U.S. Department of Energy and National Science Foundation; the Italian Istituto Nazionale di Fisica Nucleare; the Ministry of Science, Culture, and Education of Japan; the Natural Sciences and Engineering Research Council of Canada; the A. P. Sloan Foundation; and the Alexander von Humboldt-Stiftung. We thank Jonathan Rosner and James Stirling for helpful discussions.

- [8] D. Amidei *et al.*, Fermilab Preprint 94/024-E (submitted to Nucl. Instrum. Methods).
- [9] We define the transverse energy, E_T , of a calorimeter cluster as $E_T \equiv E \sin \theta$, where θ is the polar angle of the cluster with respect to the proton beam direction.
- [10] F. Abe *et al.*, Phys. Rev. D **44**, 29 (1991). Differences in the selection cuts in this analysis from that described in this reference are that we use: (i) $0.5 < E/p < 2.0$ rather than $E/p < 2.0$, (ii) $\chi_{strip}^2 < 10.0$ rather than $\chi_{strip}^2 < 15.0$, (iii) we use a cut of $\text{Had}/\text{EM} < 0.045 + 0.055(E/100)$ in the Central detector, and (iv) we do not require a charged track in the VTX for electrons in the Plug calorimeter.
- [11] An isolated electron is defined to be one for which the transverse energy in the calorimeter in the cone of radius 0.4 in $\eta - \phi$ space around the electron cluster is less than 10% of the electron transverse energy. The isolation variable used is $Iso = (E_T^{Cone} - E_T^{Cluster})/E_T^{Cluster}$.

- [18] We use $\Gamma(W \rightarrow e\nu) = (G_F/\sqrt{2})(M_W^3/6\pi)$ and $\Gamma(Z^0 \rightarrow e^+e^-) = 8(g_A^2 + g_V^2)(G_F/\sqrt{2})(M_Z^3/12\pi)$, where $8(g_A^2 + g_V^2) = [1 - 4\sin^2\theta_W + 8\sin^4\theta_W]$ for electrons. The values for M_Z , M_W , and $\sin^2\theta_W$ come from Ref.[2].
- [19] J. Rosner, M. Worah, and T. Takeuchi, Enrico Fermi Institute Preprint EFI-93-40 (1993).
- [20] A direct search for a light top that decays to a charged Higgs was undertaken by the CDF Collaboration, Fermilab Preprint 93/338-E (submitted to Phys. Rev. Lett.), but this search is dependent upon the parameter $\tan\beta \equiv v_1/v_2$, where v_1 and v_2 are the vacuum expectation values of the Higgs fields considered in the search.
- [21] We use the method of M. Aguilar *et al.* (Particle Data Group), Phys. Lett. **204B**, 1 (1990) for extracting a limit in the case of a bounded physical region.

Table I: Summary of Results.

	W events	Z events
Candidates	13796	1312
Backgrounds:		
Hadron Jets	898 ± 155	20 ± 9
$W^\pm \rightarrow \tau^\pm \nu$	473 ± 29	-
$Z^0 \rightarrow \tau^+ \tau^-$	48 ± 7	1 ± 1
$Z^0 \rightarrow e^+ e^-$	281 ± 42	-
Top	$0 + 52 - 0$	-
Total	$1700 + 171 - 163$	21 ± 9
Signal	$12096 \pm 117 + 163 - 171$	$1291 \pm 36 \pm 9$
Acceptance	0.341 ± 0.008	0.408 ± 0.005
A_W/A_Z	0.835 ± 0.013	
F_{cc}	-	0.372 ± 0.007
F_{cp}	-	0.509 ± 0.007
F_{cf}	-	0.120 ± 0.005
c_1	0.754 ± 0.011	0.754 ± 0.011
c_2	-	0.917 ± 0.008
p	-	0.909 ± 0.014
f	-	0.859 ± 0.044
ϵ_W, ϵ_Z	0.754 ± 0.011	0.729 ± 0.016
ϵ_W/ϵ_Z	1.035 ± 0.016	
Drell-Yan correction	-	1.005 ± 0.002
$\sigma B(W \rightarrow e\nu)/\sigma B(Z^0 \rightarrow e^+ e^-)$	$10.90 \pm 0.32(stat.) \pm 0.29(sys.)$	

Figure 1: (a) Observed distribution of invariant mass of e^+e^- pairs satisfying our electron selection criteria. Z^0 candidates are taken to lie in the range $66 - 116 \text{ GeV}/c^2$. (b) Observed distribution of transverse mass of the W candidates. The curves in both plots are the sum of the expected background shape and the predicted spectrum from the Monte Carlo used in the acceptance calculation.

Figure 2: The predicted value for $\Gamma(W)/\Gamma(W \rightarrow e\nu)$ from the Standard Model and this measurement. The curve is the Standard Model prediction. The solid horizontal line is our central value, the 1σ error bars are denoted by the dotted lines. The 95% C.L. upper limit is the dot-dash line. The 95% C.L. lower limit on m_{top} is $62 \text{ GeV}/c^2$.
