# Abstract

High power, stable single frequency laser sources are required for gravitational wave interferometry. The next generation of interferometers may require laser sources in the 1.3-1.65  $\mu\text{m}$  band for use with Si test masses and InGaAs photodetectors. We propose a high power cryogenic Er:YAG laser operating at 1.618  $\mu\text{m}$  for this purpose, adapting existing knowledge about cryogenic Yb:YAG lasers developed at the University of Adelaide.

To produce such a laser, further information is required about the viability of Er:YAG in high power, single frequency operation. In this thesis, I report this investigation of the spectroscopy of Er:YAG at room temperature and at cryogenic temperatures ( $\approx 77$  K) and investigate a variety of wavelengths for diode pumping of an Er:YAG slab laser.

Spectroscopy indicates that diode pumping for the 77 K laser slab will be most effective in the 1450-1480 nm absorption band, most specifically at the 1453 nm absorption peak. I describe methods for cooling a 1470 nm diode below 0  $^{\circ}\text{C}$  to pump this 1453 nm Er:YAG absorption. The cooled diode exhibits up to 9 % increase in slope efficiency and improved beam divergence compared to room temperature operation.

I then describe the construction and characterisation of CW Er:YAG lasers at both 300 K and 77 K, tuning the pump wavelength in the 1450-1480 nm band. At 300 K, I demonstrate an Er:YAG laser with 4.5 W output power when pumped with 30 W of diode power at 1468 nm, and just under 4 W of output power when pumped with 34 W of diode power at 1456 nm. Both lasers have a threshold of approximately 12 W incident pump power. The laser pumped at 1468 nm also demonstrates a greater slope efficiency relative to incident pump power: 28 % compared to 20 % when pumped at 1456 nm.

The development of a preliminary cryogenic Er:YAG laser is also reported. Despite sub-optimal mounting materials and geometries, we demonstrate a cryogenic laser with 5.5 W output power and approximately 6 W threshold under comparable pumping conditions to the 4.5 W 300 K laser pumped at 1468 nm. Unfortunately subsequent studies of the cryogenic slab laser are not comparable to the 300 K Er:YAG laser due to electrical damage to the diode that significantly reduced diode

## ABSTRACT

power and changed pumping conditions. Nevertheless, these results provide valuable information on the sensitivity of end-pumped cryogenic lasers to mounting conditions and pump focusing that are useful for a future high power design.

# Statement of Originality

I certify that this work contains no material which has been accepted for the award of any other degree or diploma in my name in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text. In addition, I certify that no part of this work will, in the future, be used in a submission in my name for any other degree or diploma in any university or other tertiary institution without the prior approval of the University of Adelaide and where applicable, any partner institution responsible for the joint award of this degree.

I give consent to this copy of my thesis when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968.

I also give permission for the digital version of my thesis to be made available on the web, via the University's digital research repository, the Library Search and also through web search engines, unless permission has been granted by the University to restrict access for a period of time.

# Acknowledgements

First and foremost, I would like to thank my supervisors Jesper Munch and Peter Veitch. Thank you for the time you've spent helping me find the physics in the midst of the laser engineering work we do, and thank you for your expertise both throughout my project and with editing this thesis. I'd also like to thank Miftar Ganija for all he's contributed to this project: for finding a path when I was lost, and for teaching me to squeeze every last drop from our equipment.

I'd like to thank David Hosken, for his support in helping me build my confidence in the lab, and for all our conversations about the ins and outs of working in research. Life is not a dress rehearsal, so it's been great to have a guide.

I'm grateful for the assistance of so many other University students and staff throughout my studies, for their contributions great and small. Thank you to Blair Middlemiss and Bob Chivell for helping me find (or make!) equipment, and putting up with me driving the BBQ through the workshop. Thank you to Neville Wild, for helping me troubleshoot all sorts of electronics. And thank you to all of the office staff for the administrative tasks that keep everything running smoothly for research students.

Best of luck to all my fellow students undertaking similar studies. Special thanks to Ka, Ori and Elli who've shared office space, lab experiences and stories, and to Fiorina, Sebastian and Ashby who helped me keep it together to make the OSA and KOALA 2014 a huge success.

Finally, thank you to my friends and family who have been supportive of me and tolerant of my long absences from face-to-face contact. Thank you to the Blues Underground (and all of my blues family) for giving me something to look forward to at the end of a long week. Last of all, falling into nearly every category, special thanks to Finn for his tireless support of me through conferences, through intense weeks in the lab, through my long nights editing this thesis, and through anything life could throw at me.

# List of Symbols

$\alpha$	Absorption coefficient ( $\text{cm}^{-1}$ )
$\alpha_T$	Coefficient of linear thermal expansion
$\beta$	Inversion fraction
$\lambda$	Wavelength (general)
$\lambda_l$	Laser wavelength
$\lambda_p$	Pump wavelength
$\sigma$ or $\sigma_a$	Absorption cross-section ( $\text{cm}^2$ )
$\sigma_e$	Emission cross-section ( $\text{cm}^2$ )
$\theta$	Far-field divergence half-angle
$\Omega$	An arbitrary phase
$A$	A positive constant
$c$	The speed of light
$\frac{dn}{dT}$	Change of material refractive index with respect to temperature
$E(x, T)$	The energy of an excited state $x$ , at temperature $T$
$E_1$ and $E_2$	The electric field amplitude of the reference arm and slab arm of the interferometer respectively
$f$	Used to represent the focal length of a lens
$f_L$ and $f_U$	Fractional occupation of the lower and upper lasing states respectively
$F(x)$	Boltzmann occupation factor of a state $x$
$G$	Laser gain, used in the form $I_{out} = I_{in} \exp(Gz)$
$\hbar$	The reduced Planck's constant
$I$	Intensity
$I_{in}$	Input intensity, before gain or absorption has been applied. Used to represent the background spectrum.
$I_{out}$	Output intensity, after gain or absorption has been applied. Used to represent the spectrum of a sample.
$k$	Boltzmann's constant
$k_x$	The wave number

## LIST OF SYMBOLS

$K$	Thermal conductivity
$L$	Length
$L_1$ to $L_4$	The lowest four energy “bands” in Er:YAG, see Figure 2.2
$m$	An integer
$M^2$	Beam quality, “times diffraction limited”
$n$	Refractive index
$N$	Number density of ions in the material(in $\text{cm}^{-3}$ )
$N_L$ and $N_U$	Number density of ions in the lower and upper lasing states respectively
$P_{change}$	The change in power from the mean value $P_{signal}$ , used to calculate intensity stability
$P_{signal}$	The mean value of the laser output power, used to calculate intensity stability
$t$	Time
$T$	Temperature
$\text{TEM}_{00}$	The fundamental Transverse ElectroMagnetic mode
$w_0$	Radial beam width
