## **Abstract**

A new non-perturbative, gauge-invariant, exact, finite model of quantum chromodynamics, with a particular choice of renormalization is applied to high energy elastic pp-scattering. Gauge invariance is insured by explicit cancellations of all gauge dependent gluon propagators. The result is the entire infinite sum of all gluon exchanges between two quarks/(anti)quarks.

With a particular choice for renormalization, this model is tested against hadron elastic scattering at ISR energies with favorable results. The differential cross- section deduced from this model displays a diffraction dip that compares very well with those of experiments. Calculation of infinite loop chains under our renormalization scheme fits experimental data rather favorably. Extension to total scattering cross-section is expected.

## Introduction

### 1.1 Yang Mills and QCD

Yang-Mills theory, also known as "non-abelian gauge theory" [61] has an interesting history from the work of gauge symmetry that evolved from the work of Hermann Weyl [50].

Yang-Mills equations have common properties with Maxwell equations in that they provide classical description of massless waves. In the 1950's when Yang-Mills was discovered, it was already known that Quantum Electrodynamics gives extremely accurate experimental comparisons. However, the massless nature of classical Yang-Mills waves is an obstacle in applying Yang-Mills to nuclear forces, where forces are short ranged and particles are massive. In the case of the weak force, Glashow-Salam-Weinberg's electroweak theory used gauge group  $H = SU(2) \times U(1)$ . The massless nature of classical Yang-Mills waves were avoided with the addition of the Higgs field.

In the case of the strong force, the discovery of Asymptotic freedom, rather than the addition of fields to quantum Yang-Mills [37, 54]. Asymptotic freedom means that at short distances, fields display quantum behaviors similiar to its classical ones. At long distances, however, classical theory is not a good indicator for the quantum behaviors. Asymptotic freedom together with other experimental and theoretical results in the 1960's and 1970's made it possible to describe the strong force by a non-abelian gauge theory with gauge group  $G = SU(3)$ . The additional fields

describe quarks with spin 1/2 that are perhaps analogous to the electron. Quarks, however transform under the representation of  $SU(3)$ . This non-abelian gauge theory of the strong force is called Quantum Chromodynamics (QCD).

For QCD to describe the strong force successfully, it must have at the quantum level the following three properties as described in one of the Millenium Problems by the Clay Mathematics Institute:

1) It must have a mass gap,  $\Delta > 0$ , such that every excitation of the vacuum has energy at least  $\Delta$ . 2) It must have "quark confinement," that is, even though the theory is described in terms of elementary fields, such as quark fields, that transform non-trivially under  $SU(3)$ , the physical particle states – such as the proton, neutron, and pion – are  $SU(3)$ -invariant. 3) It must have "chiral symmetry breaking," which means that the vacuum is potentially invariant (in the limit that the quark-bare masses vanish) only under certain subgroup of the full symmetry group that acts on the quark fields.

The first point insures that strong forces are short ranged, the second point explains why quarks are never observed experimentally except in bound states, the third point is needed to account for the current algebra of soft pions.

Both experiment and computer simulations suggest strongly that QCD does have the three properties. QCD, however, are not fully understood theoretically. "There does not exist a convincing, whether or not mathematically complete, theoretical computation demonstrating any of the three properties in QCD, as opposed to a severly simplified truncation of it." [40] Despite many empirical successes in QCD, many fundamental questions remain unsolved. Questions include hadronization, color confinement, the behavior of QCD coupling at small momenta, asymptotic  $n!$  growth of the perturbation theory, also known as renormalon phenomena, the diffractive phenomena, a fundamental understanding of the soft and hard pomeron in high energy scattering, and the conflict between QCD vacuum structure and the small size of the cosmological constant [9].

## 1.2 Running Couplings

QCD running coupling can be obtained from integrating the differential equation

$$\mu^2 \frac{d\alpha_s}{d\mu^2} = \beta(\alpha_s) \quad (1.1)$$

rewritten as

$$\ln \frac{\mu^2}{\mu_0^2} = \int_{\alpha_s(\mu_0^2)}^{\alpha_s(\mu^2)} \frac{d\alpha}{\beta(\alpha)} \quad (1.2)$$

The resulting form is

$$\alpha_s(\mu^2) = \frac{1}{\beta_0 \ln(\mu^2/\Lambda^2)} \quad (1.3)$$

The dimensional scale  $\Lambda$  keeps track of initial parametrization  $(\mu_0, \alpha_s(\mu_0^2))$ . The value of  $\Lambda$  must be extracted from experimental measurement of  $\alpha_s$  for a given reference scale. This emergence of a scale parameter, referred to as dimensional transmutation, breaks the scale invariance of massless theories. This scale parameter is believed to be associated the hadron size.  $\Lambda$  is the scale about which the coupling (one-loop) diverges, the Landau ghost, and where perturbation theory becomes meaningless. This dimensional scale is scheme-dependent and receives further correction at each loop level [55].

## 1.3 Confinement and conformal algebraic structures'

In Brodsky and company's work, Light Front (LF) Hamiltonian theory provided a rigorous relativistic and frame independent framework for non-perturbative QCD and understanding color confinement. For QCD(1 + 1), eigenstates for baryons and mesons at zero quark mass is determined in units of its dimensionful coupling with the Discretized Light Cone Quantization (DLCQ) [52, 51]. In the case of 3 + 1 dimension, QCD's coupling is dimensionless, thus, it is not clear what sets the hadron mass. Instead, the work by de Alfaro, Fubini and Furlan (dAFF) can generate a mass scale and a confinement potential without changing the conformal invariance of the action. [48]. Thus, effective LF confining potential can be obtained by extending the

results found by dAFF to light-front dynamics and to the embedding space [11].

Brodsky and company and work in Charmonium showed that an effective harmonic potential in the light-front form of dynamics, for light quark masses, corresponds to a linear potential in the usual instant-form [60, 17]. These results give the prediction of linear Regge trajectories in the hadron mass square for small quark masses, in agreement with observations for light hadrons. 4 dimensional light-front dynamics combined with 5 dimensional  $AdS_5$ , with the extraction of mass scale from dAFF in  $1 + 1$  dimension gives rise to  $SO(2, 1)$ , an isometry group of  $AdS_2$ . Stated another way, the emergence of a mass scale comes from the remarkable connection between semiclassical light-front dynamics in four-dimension with gravity in higher dimensional AdS space, with constraints imposed by the dAFF one dimensional quantum field theory. [10].

## 1.4 Hadrons and Meson Spectrum

With LF Hamiltonian, hadronic states are arrived at in:

$$[-\frac{z^{d-1-2J}}{e^{\varphi(z)}}(\frac{e^{\varphi(z)}}{z^{d-1-2J}}\partial_z) + \frac{(mR)^2}{z^2}]\Phi_J(z) = M^2\Phi_J(z), \quad (1.4)$$

where invariant hadron mass  $P_\mu P^\mu \equiv \eta^{\mu\nu} P_\mu P_\nu \equiv M^2$  The AdS mass  $m = \mu_{eff} = \mu$  in the equation is a constant that is determined from the mapping of the light-front Hamiltonian.  $m$  maps to the Casimir operator of the orbital angular momentum in the light front. See Figure 1-2.

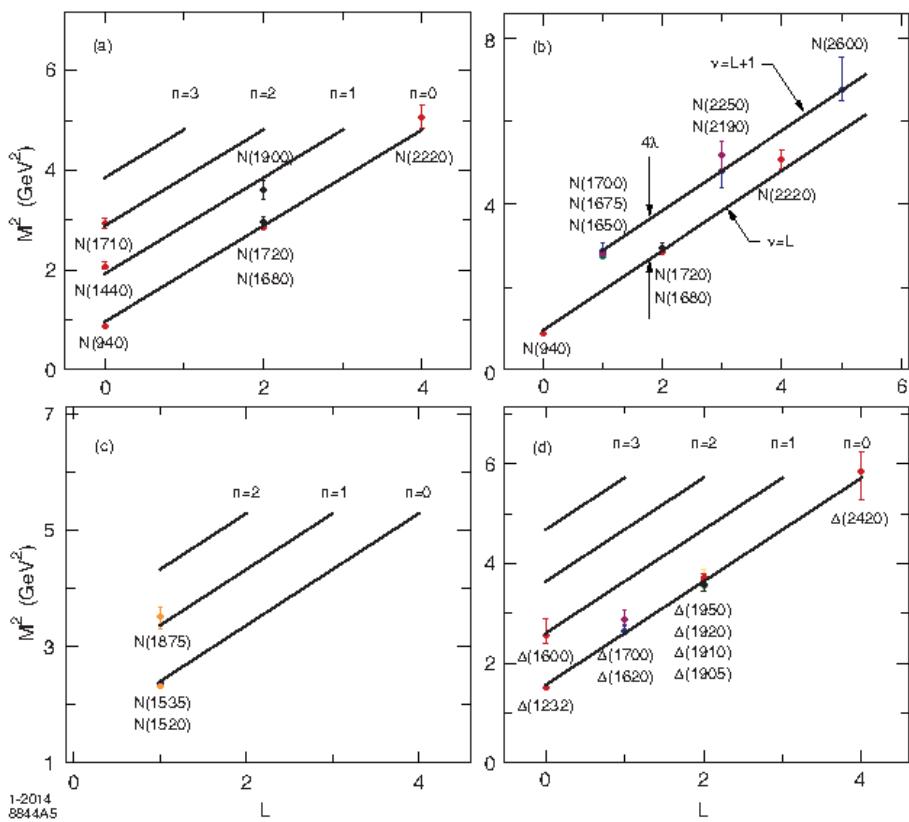

Figure 1-1: Meson spectrum [10]

# Chapter 2

## High Energy Scattering

The Balitsky-Fadin-Kuraev-Lipatov (BFKL) [44, 20, 43, 42, 5, 6] formalism enables the logarithms appearing in scattering amplitudes with large center of mass energy,  $\sqrt{s}$  and fixed momentum transfer  $\sqrt{-t}$  to be summed. Calculations of strong coupling high energy scattering at HERA, the Tevatron and LHC has used DGLAP and BFKL [56]. The Dokshitzer-Gribov-Lipatov-Altarelli-Parisi, DGLAP equation and the Balitsky-Fadin-Kuraev-Lipatov (BFKL) equation formed the basis for current understanding of high-energy scattering in quantum chromodynamics. See Figure [?].

Without an analytic QCD solution, calculations had to resort to studying unitarity and analyticity constraints on scattering amplitudes, combined with the work of Tullio Regge. Gribov, Lipatov and others developed the leading logarithm approximation to processes at high-energies. This is central to perturbative QCD for strong interactions. Reggeon field theory was checked and confirmed with QED experiments.

Experiments in the 1960s at SLAC had showed Bjorken scaling in deep inelastic lepton-hadron scattering. Gribov attempted to see if Bjorken scaling can be derived from QFT. For large momentum transfer, leading Feynman diagrams in QED gave rise to the logarithmically enhanced contributions to the cross section at fixed values of the Bjorken variable,  $x = q^2/(s + q^2)$  between 0 and 1 [36].

Lipatov showed that the gauge vector boson in Yang-Mills theory is reggeized with radiative corrections included [45]. The vector boson becomes a moving pole in the complex angular momentum plane near  $j = 1$ . In QCD, this pole corresponds to color

exchange. The exchange of two or more reggeized gluons leads to colorless exchange in the t-channel. This exchange with vacuum quantum numbers is a Pomeron, and with non-vacuum ones is an Odderon.

Lipatov and collaborators showed that Pomeron correspond to a regge cut, and not a pole in the complex angular momentum plane.

## 2.1 BFKL and DGLAP

Quantum field theory is the heart of QCD, however, attempts towards solving QFT for strong interactions have been difficult. Some fifty years ago, efforts have been made to circumvent traditional QFT by focusing on unitarity and analyticity on scattering amplitudes, combined with extensions to Tullio Regge's work on connecting complex angular momentum to relativistic theory. Balitsky, Fadin, Kuraev and Lipatov (BFKL), over two decades ago, set out to determine the high-energy behavior of the scattering of hadronic objects within perturbative QCD. They found terms going as  $(\alpha_s \ln s)^n$ , where  $s$  is the squared centre-of-mass energy. Since the factor  $\ln s$  can compensate the smallness of  $\alpha_s$ , it was necessary to sum the entire series of leading logarithmic,  $LL$ , terms. The resulting cross-section increases as a power of  $s^2$ . For typical values of  $\alpha_s \approx 0.2$ , this power is of the order of 0.5 [42, 5].

Much experimental effort has been devoted towards observing this phenomenon in the 1990's, however, experiments showed that the cross sections rise is much slower than  $s = 0.5$ .

The solution to this problem was to have been in determining the next-to-leading corrections to the BFKL equation, terms  $\alpha_s(\alpha_s \ln s)^n$ . After much effort, however, the next-to-leading order showed to be much smaller and the leading contribution, and, in fact, turned out not even positive definite [57].

Lipatov and collaborators showed that the Pomeron corresponds to a cut, and not a pole, in the complex angular momentum plane. Lipatov discovered beautiful symmetries in the BFKL equation. This enabled him to obtain solutions in terms of the conformal-symmetric eigenfunctions. This completed the construction of the

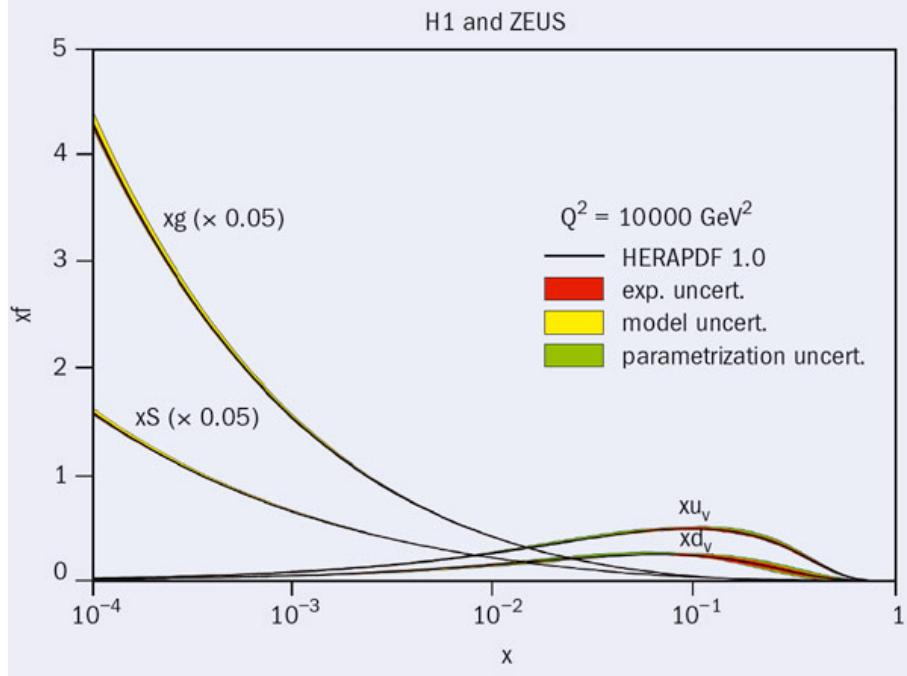

Figure 2-1: DGLAP equations allows the extraction of parton distribution functions from data at the electron-proton collider HERA. The proton-parton densities have been extracted from the combined H1 and ZEUS measurements in this figure, for  $q^2 = 10,000 \text{ GeV}^2$ . This corresponds to  $W$  production at the LHC.  $xg$  is the gluon term that dominates the proton content at low Bjorken- $x$  [41].

fundamental entity in high-energy physics in the bare Pomeron in QCD [46].

## 2.2 Donnachie and Landshoff

Regge theory has been hugely successful when compared with experimental data [16]. However there is significant gap in its understanding. Only exchanges of single particles can be calculated after five decades. Double or high exchanges has yet to be done. The accurate description of experimental data can only be achieved with the introduction of an exchange, the Pomeron, not obviously associated with particle exchange. According to Regge theory, particle exchange contributes simple power behavior  $s^\epsilon$  to total cross sections. Donnachie and Landshoff, three decades ago, introduced just two powers to fit all hadron-hadron total cross sections. They showed with  $\epsilon \approx 0.08$  corresponds to pomeron exchange and  $\epsilon_R \approx \frac{1}{2}$  to nearly degenerate  $\rho$ ,  $\omega$ ,  $f_2$ ,  $a_2$  exchange.

With deep inelastic  $ep$  scattering at small  $x$  from HERA, Donnachie and Landshoff introduced a second pomeron, the hard pomeron. This put the conventional DGLAP evolution analysis at small  $x$  in sound footing [16]. Without the second pomeron, unitarity would be violated as the forward amplitude would grow very large with increasing energy. Additional terms beyond  $P$  and  $PP$  would be ultimately necessary for higher energies to prevent the total cross section from becoming negative because the two pomeron  $PP$  term is negative, to preserve unitarity, but grows much more rapidly than  $P$ .

For the total cross section,  $\sigma_{total} = \text{Im } A(s, 0)$ , Donnachie and Landshoff has

$$A(s, t) = -\frac{X_P F_P(t)}{2\nu} e^{-\frac{1}{2}i\pi\alpha_P(t)} (2\nu\alpha'_P)^{\alpha_P(t)} - \frac{X_+ F_+(t)}{2\nu} e^{-\frac{1}{2}i\pi\alpha_+(t)} (2\nu\alpha'_+)^{\alpha_+(t)} \mp \frac{iX_- F_-(t)}{2\nu} e^{-\frac{1}{2}i\pi\alpha_-(t)} (2\nu\alpha'_-)^{\alpha_-(t)} \quad (2.1)$$

where  $\alpha_i(t) = 1 + \epsilon_i + \alpha'_i t$   $i = P, \pm$  and  $F(t) = Ae^{at} + (1 - A)e^{bt}$ , see figure 2-2

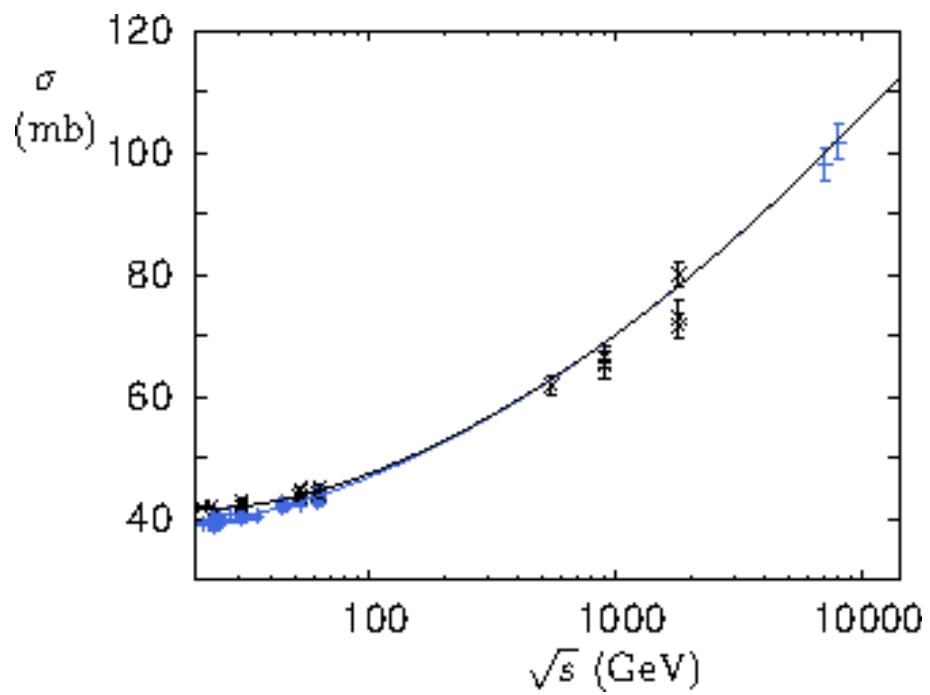

Figure 2-2: Total cross section with Reggeon and Pomeron [16]

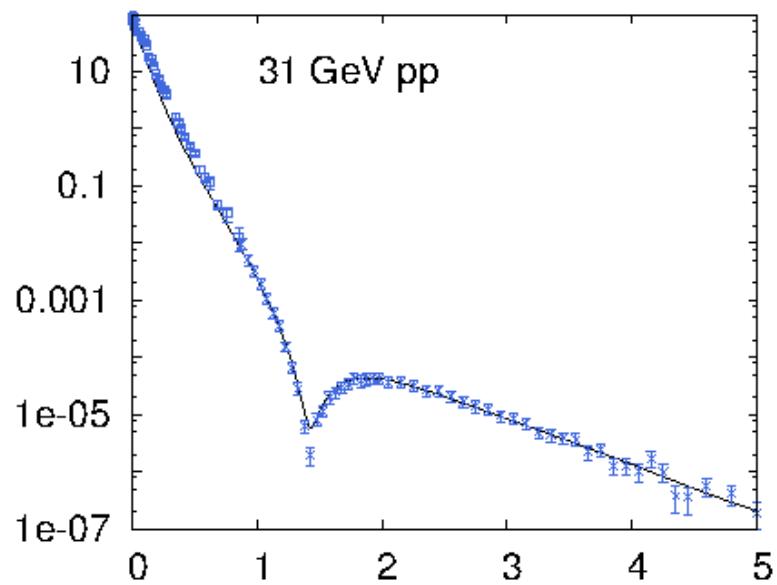

Figure 2-3: Differential cross section for elastic pp with Reggeon and Pomeron [16]

## 2.3 AdS/CFT - Tan and company.

In recent years, the AdS/CFT correspondence has been heavily investigated for QCD processes. Curved space string theory was first used to describe the classical Regge regime, where  $s > \Lambda_{QCD}^2$  and the BFKL regime. A coherent treatment of the Pomeron based on AdS/CFT was presented by Brower, Polchinski, Strassler and Tan in 2006 [12]. String theory in flat space generally disagree with QCD, however, in the classic Regge regime, where  $s \gg \Lambda_{QCD}^2$  and  $|t| \leq \Lambda_{QCD}^2$ , QCD scattering processes shows amplitudes similar to Regge behavior or that of flat-space classical string theory. For  $s \gg -t \gg \Lambda_{QCD}$ , string amplitudes follows a linear Regge trajectory while QCD does not. The asymptotic Regge regime is important because it accounts for most of total cross-sections and differential cross-sections at small angles, on the other hand however, direct perturbative computation nor lattice QCD methods can obtain QCD amplitudes. In string theory, the Pomeron is the object exchanged at tree level scattering in the Regime regime. That is, the graviton's Regge trajectory. Multi-Pomeron exchange becomes dominant as  $s \rightarrow \infty$ , and as such, non-perturbative approach to Pomerons is needed [13, 14].

Lipatov also considered the BFKL and DGLAP equations in  $N=4$  theory and computed the anomalous dimensions of various operators. The high symmetry of  $N=4$  SYM allowed calculations to be made to unprecedented high orders and the results were then compared with the predictions of string theory. This facilitated the study of integrable structures [47].

Lipatov established that the gluon production amplitudes in the planar approximation can have Mandelstam cut contributions in the multi-regge kinematics at some physical regions. The wavefunction of these states, in the adjoint representation, satisfy BFKL-like equation. They are integrable in leading logarithmic approximation and have the property of holomorphic factorization [47].

The resulting holomorphic hamiltonian coincides with an integrable open Heisenberg spin model's hamiltonian. A simple recurrent relation is obtained for the Baxter-Sklyanin equation for this model in terms of  $\Gamma$ -functions.

In 2007, Tan and company derived the Eikonal approximation for multiple Pomeron exchanges. Single Pomeron and multiple graviton exchange in AdS are generalized to consider unitarity and saturation in the conformal regime. This Eikonal indicates that the Froissart bound is satisfied and saturated [13, 14].

Alday and Maldacena in 2007 also wrote down gluon scattering amplitudes at strong coupling in  $N = 4$  super Yang Mills using gauge/string duality [1]. Solutions were arrived at by finding classical string configurations with boundary conditions determined by gluon momenta. These solutions are infrared divergent. The gravity version of dimensional regularization was used to define finite quantities. These results are in agreement with similar work by Bern, Dixon and Smirnov [7].

## 2.4 Eikonal Derivation from Martin Perl Page 41-43

Starting with the relativistic wave equation

$$[\nabla^2 + k^2]\psi(r) = U(r)\psi(r) \quad (2.2)$$

Following derivation given by Glauber (2GL), where  $U(r)$  is complex. With incident wave  $\psi_{inc}(r)$ , moving in direction  $+z$ , being written as

$$\psi_{inc}(r) = e^{ikz}\phi(r) \quad (2.3)$$

where  $\phi(r) = 1$  at  $z = -\infty$ . Inserting  $\psi_{inc}(r)$  into above gives

$$[2ik\frac{d}{dz} + \nabla^2]\phi(r) = U(r)\phi(r). \quad (2.4)$$

Assume the potential varies slowly with  $r$  that the second derivative can be neglected, or

$$|\nabla^2\phi(r)| \ll |2ik\frac{d\phi(r)}{dz}| \quad (2.5)$$

Then we obtain

$$2ik \frac{d\phi(r)}{dz} = U(r)\phi(r) \quad (2.6)$$

and

$$\phi(r) = \exp\left[\frac{-i}{2k} \int_{-\infty}^z U(x, y, z') dz'\right]. \quad (2.7)$$

Insert this expression for  $\phi(r)$  into  $\psi_{inc}(r)$  gives

$$\psi_{inc}(r) = e^{ikz} \exp\left[-\frac{i}{2k} \int_{-\infty}^z U(x, y, z') dz'\right]. \quad (2.8)$$

From  $\psi(r) = \psi_{inc}(r) + \psi_{scat}(r)$ , and  $R = r - r'$  where

$$\psi_{scat}(r) = \frac{1}{4\pi} \int d^3r [U(r') \psi(r') \frac{e^{ikR}}{R}] \quad (2.9)$$

We obtain

$$\psi_{scat} = -\frac{1}{4\pi} \int d^3r [U(r) e^{ikz} \exp\left(-\frac{i}{2k} \int_{-\infty}^z U(x, y, z') dz'\right) \frac{e^{ikR}}{R}] \quad (2.10)$$

Remembering that  $\psi_{scat}(r) = f(\theta) \frac{e^{ikr}}{r}$  with  $f(\theta) = -\frac{1}{4\pi} \int d^3r [U(r') e^{i(k-k') \cdot r'}]$ ,

we arrive at the eikonal approximation

$$f(\theta) = -\frac{1}{4\pi} \int d^3r [e^{i(k-k') \cdot r} U(r) \exp\left(-\frac{i}{2k} \int_{-\infty}^z U(x, y, z') dz'\right)]. \quad (2.11)$$

For  $b = z$ ,  $(k - k') \cdot r = q \cdot r \approx q \cdot b$ ,

above becomes

$$f(\theta) = \frac{k}{2\pi i} \int d^2b e^{iq \cdot b} \exp\left[\frac{-i}{2k} \int_{-\infty}^{+\infty} U(b, z) dz\right] - 1 \quad (2.12)$$

If we define  $\chi(b) = \chi_i(x, y, z = \infty)$ , we get the common form of the eikonal model:

$$f(\theta) = \frac{k}{2\pi i} \int d^2b e^{iq \cdot b} [e^{i\chi(b)} - 1] \quad (2.13)$$

see "High Energy Hadron Physics" by Martin L. Perl [53].

# Chapter 3

## Halpern Functional Integral

### 3.1 Field-Strength Formulation of Quantum Chromodynamics

In 1977, Halpern in an attempt to extend non-abelian gauge theories in space-time dimensions to  $D \geq 3$  provided the follow work in this section. Non-abelian gauge theories is reformulated in terms of field strengths and the details for ( $D = 4$ ) QCD is written down [38, 39].

Starting with the action for QCD,

$$\begin{aligned} S_1 &= \int d^D x \left[ \frac{1}{2} G_{\mu\nu}^i F_{\mu\nu}^i - \frac{1}{4} G_{\mu\nu}^i G_{\mu\nu}^i + \psi^\dagger (\not{\partial} + M + ig \not{\mathcal{N}}) \psi \right], \\ F_{\mu\nu}^i &\equiv \partial_\mu V_\nu^i - \partial_\nu V_\mu^i - g f^{ijk} V_\mu^j V_\nu^k, \\ \not{\mathcal{N}} &\equiv \gamma_\mu V_\mu^a \frac{\lambda_a}{z} \end{aligned} \tag{3.1}$$

For the Generating Functional, we integrate  $e^{S_1}$  over all  $G_{\mu\nu}^i, V_\mu^i, \psi, \psi^\dagger$ . After quadratic

integration over the  $V_\mu^i$ , we obtain the field-strength action,

$$\begin{aligned}
S = & \int d^D \chi \left[ \frac{1}{2g} (\partial_\rho G_{\mu\nu}^i - g J_\mu^i) (\mathcal{G}^{-1})_{\mu\nu}^{ij} (\partial_\lambda G_{\lambda\nu}^j - g J_\nu^j) \right. \\
& - \frac{1}{4} G_{\mu\nu}^i G_{\mu\nu}^i + \psi^\dagger (\not{\partial} + M) \psi \\
& \left. - \chi_{\mu\nu}^i \frac{g}{2} \mathcal{G}_{\mu\nu}^{ij} \chi_\nu^j \right], \\
J_\nu^i \equiv & i \psi^\dagger \gamma_\mu \frac{\lambda^i}{2} \psi.
\end{aligned} \tag{3.2}$$

$\chi_{\mu\nu}^i$  is our familiar auxiliary field, much like a Faddeev-Popov field, representing  $(\det \mathcal{G})^{-1/2}$ . In the case of  $N = 2$ ,  $D = 4$ , we have

$$(\mathcal{G}^{-1})^{ij} = \tilde{G}^j G^i K^{-1} \tag{3.3}$$

where  $K \equiv G^1 \tilde{G}^2 G^3 - G^3 \tilde{G}^2 G^1$  and  $\tilde{G}_{\mu\nu}^i \equiv \frac{1}{2} \epsilon_{\mu\nu\rho\sigma} G_{\rho\sigma}^i$ ,  $\epsilon_{0123} = +1$ .

In the self dual sectors for  $K$ ,  $G^i = \pm \tilde{G}^i$ ,  $G_{0l}^i \equiv E_l^i$ , we obtain:

$$\begin{aligned}
K_{\mu\nu} = & \delta_{\mu\nu} \xi, \xi \equiv \frac{1}{3} \epsilon^{\alpha\beta\gamma} \epsilon_{ijk} E_i^\alpha E_j^\beta E_k^\gamma, \\
(\mathcal{G}^{-1})^{ij} = & \pm \xi^{-1} G^j G^i.
\end{aligned} \tag{3.4}$$

Under gauge transformations

$$\begin{aligned}
V_\mu^i & \rightarrow O^{ia} V_\mu^a + \frac{1}{2g} f^{jk} O^{ja} \partial_\mu (O^T)^{ak}, \\
G_{\mu\nu}^k & \rightarrow O^{kl} G_{\mu\nu}^l, \\
\mathcal{G}_{\mu\nu}^{ij} & \rightarrow O^{il} \mathcal{G}_{\mu\nu}^{lm} (O^T)^{mj}, \\
(\mathcal{G}^{-1})_{\mu\nu}^{ij} & \rightarrow O^{ib} (\mathcal{G}^{-1})_{\mu\nu}^{ba} (O^T)^{aj}
\end{aligned} \tag{3.5}$$

, the field equations are invariant. The action, however,

$$S = \int d^4 \chi \left[ \frac{1}{2g} (\partial G \mathcal{G}^{-1} \partial G) - \frac{1}{4} G^2 - \chi \frac{g}{2} \mathcal{G} \chi \right] \tag{3.6}$$

is not explicitly gauge-invariant.

To regain explicity gauge-invariance, we use identities,

$$\begin{aligned}
\partial_\lambda G_{\mu\nu}^i (\mathcal{G}^{-1})_{\mu\nu}^{ij} \partial_\rho G_{\rho\nu}^j &= G_{\mu\nu}^i \epsilon^{ijk} \mathcal{J}_\mu^j \mathcal{J}_\nu^k \\
&= \partial_\lambda G_{\lambda\mu}^i \mathcal{J}_\mu^i \\
&= -G_{\lambda\mu}^i \partial_\lambda \mathcal{J}_\mu^i + \partial_\lambda (G_\lambda^i \mathcal{J}_\mu^i).
\end{aligned} \tag{3.7}$$

With appropriate choices of the second and last term in Eq. 3.7 and dropping the surface term, we obtain explicit gauge-invariant form,

$$S = \int d^4\chi \left[ -\frac{1}{2g} G \mathcal{F}(\mathcal{J}(G)) - \frac{1}{4} G^2 - \chi \frac{g}{2} \mathcal{G} \chi \right]. \tag{3.8}$$

Or

$$S = \int d^4\chi \left[ -\frac{1}{4} \left( G + \frac{\mathcal{F}}{g} \right)^2 + \frac{1}{8g^2} (\mathcal{F} \pm \tilde{\mathcal{F}})^2 \mp \frac{1}{4g^2} \mathcal{F} \tilde{\mathcal{F}} \right] \tag{3.9}$$

[38, 39]. At the saddle point, the first term in Eq. 3.8 vanishes and at fixed  $\int d^4\chi \mathcal{F} \tilde{\mathcal{F}}$ , the action is minimum only if  $\mathcal{F} \pm \tilde{\mathcal{F}} = 0$  and  $G = \pm \tilde{G}$ . Rerranging Eq. 3.8 and Eq. 3.9 brings us to the form we shall use in our formalism,

$$S = \int d^4\chi \left[ +\frac{1}{2g} G \chi + \chi^2 \right]. \tag{3.10}$$

# Chapter 4

## Casimir Invariants

### 4.1 Casimir Invariants, $C_2$ and $C_3$

In non-relativistic Quark Models and in non-perturbative Schwinger mechanism, the dependence on the cubic Casimir operator,  $C_3$  is important. In strong coupling fermionic QCD, the Green's functions and related amplitudes requires not just the  $SU_c(3)$  quadratic Casimir operator,  $C_{2f}$  but also this  $C_3$ .  $C_3$  accounts for the full algebraic content of the rank-2 Lie algebra of  $SU_c(3)$  [29].

As pointed out by Grandou, it is remarkable that  $C_3$  has been unnoticed for so long. Perhaps that is because numerically,  $C_3$  only account for sub-leading effects [34].

### 4.2 Non-Perturbative Fermionic Green's Functions

In perturbation theory, all scattering processes are proportional to either  $C_A = N_c$  and/or  $C_F = (N_C^2 - 1)/2N_c$  [35]. In other words, processes are proportional to the quadratic Casimir operator eigenvalue  $C_2(R)$  in the adjoint and fundamental representations.  $C_2(R)$  is defined as:

$$C_2(R) = \sum_{a=1}^8 T_a^2(R) \tag{4.1}$$

where  $T_a(R)$  are the  $SU_c(3)$  Lie algebra generators for a given representation  $R$ .

In addition to perturbative calculations, non-perturbative QCD models such as the MIT bag model, the Stochastic Vacuum Model (SVM), and Lattice QCD comply with these  $C_2(R)$  dependencies.

In strong coupling where  $g \gg 1$ , the amplitude for Quark(antiQuark)/Quark(antiQuark) scattering amplitude using Random Matrix Theory is given by:

$$\begin{aligned}
& (-16\pi \frac{m^2}{E^2})^N \sum_{\text{monomials}} (\pm 1) \text{Tr} \prod_{1 \leq i \leq N}^{\sum q_i = N(N-1)/2} [1 - i(-1)^{q_i}] \\
& \times C \int dp_1 \dots dp_{N(N-1)/2} f(p_1, \dots, p_{N(N-1)/2}) \int_0^{+\infty} d\alpha_1^i \frac{\sin[\alpha_1^i(\mathcal{OT})_i]}{\alpha_1^i} \int_0^{+\infty} d\alpha_2^i \frac{\sin[\alpha_2^i(\mathcal{OT})_i]}{\alpha_2^i} \\
& \times G_{34}^{23} \left( iN_c \left( \frac{\alpha_1^i \alpha_2^i}{g\varphi(b)} \right)^2 \frac{\hat{s}(\hat{s} - 4m^2)}{2m^4} \middle| \begin{array}{cccc} \frac{3-2q_i}{4}, & \frac{1}{2}, & 1, & \\ 1, & 1, & \frac{1}{2}, & \frac{1}{2} \end{array} \right), \tag{4.2}
\end{aligned}$$

where we have used the eikonal and quenched approximations, assumed single species of quarks of mass  $m$ .

$\mathcal{O} = \mathcal{O}(\dots, p_j, \dots)$  is an orthogonal  $N \times N$  matrix specified by the  $N(N-1)/2$  parameters  $p_j s$ , with  $N = D \times (N_c^2 - 1)$ ,  $D$ , the number of space-time dimensions; that is  $N = 32$  [38, 39]. The distribution  $f(\dots, p_j, \dots)$  defines the *Haar measure* of integration over the orthogonal group  $O_N(\mathbb{R})$ , and the constant  $C$  (the normalization) is the inverse of the  $O_N(\mathbb{R})$ -volume.  $\mathcal{O}$ , (the  $N \times N$  orthogonal matrices), acts on  $N$ -vector of matrices  $\mathcal{T} = (1, 1, 1, 1) \otimes T = (T, T, T, T)$ , i.e.  $\mathcal{T}$  is made out of  $D = 4$  copies of the full set  $T$  of  $SU_c(3)$  generators, with the fundamental representation:  $T = \{t_1, t_2, \dots, t_7, t_8\}$ , where  $t_a = \lambda_a/2$  is the standard Gell-Mann matrices [62]. This step allows one to perform a series of exact integrations.

$G_{34}^{23}$  is the Meijer special Functions [34]. The Meijer function depends on an array of parameters, one of them involving an integer  $q_i$ , with  $1 \leq i \leq N$  and  $0 \leq q_i \leq N(N-1)/2$ . The power of  $q_i$  comes from the expansion of a *Vandermonde determinant* into a sum of monomials.

Eq. 4.2 can now be rearranged to give,

$$\begin{aligned} & \pm \left( -\frac{16\pi^2 m^2}{E^2} \right)^N \sum_{\text{monomials}} \left\langle \prod_{i=1}^N [1 - i(-1)^{q_i}] \right. \\ & \times \left[ \frac{\sqrt{2iN_c} \sqrt{\hat{s}(\hat{s} - 4m^2)}}{m^2} \right] \frac{[(\mathcal{OT})_i]^{-2}}{g\varphi(b)} \\ & \times G_{03}^{30} \left( \left[ \frac{g\varphi(b)}{\sqrt{32iN_c}} \frac{m^2}{\sqrt{\hat{s}(\hat{s} - 4m^2)}} \right]^2 \left[ (\mathcal{OT})_i \right]^4 \middle| \frac{1}{2}, \frac{3+2q_i}{4}, 1 \right) \left. \right\rangle_{O_N(\mathbb{R})}, \quad (4.3) \end{aligned}$$

where the large brackets denote the orthogonal group  $O_N(\mathbb{R})$ . It is this group that displays the full algebraic content of rank-2  $SU_c(3)$  color algebra. The matrix values of the Meijer's function,  $G_{03}^{30}$  is,

$$z_i \equiv \lambda [(\mathcal{OT})_i]^4, \quad \lambda \equiv \left( \frac{g\varphi(b)}{\sqrt{32iN_c}} \frac{m^2}{\sqrt{\hat{s}(\hat{s} - 4m^2)}} \right)^2. \quad (4.4)$$

For  $g \gg 1$  and  $z_i \ll 1$  above can be rewritten as cite,

$$\pm \left( -\frac{4\pi^2 m^2}{E^2} \right)^N \left\langle \prod_{i=1}^N [1 - i(-1)^{q_i}] \sum_{h=1}^3 A_i^h z_i^{b_h - \frac{1}{2}} (1 + O_{ih} z_i + \mathcal{O}(z_i^2)) \right\rangle_{O_N(\mathbb{R})}. \quad (4.5)$$

The matrix-valued argument  $z_i$  is on the order of  $[(\mathcal{OT})_i]^4$ . and the orders  $z_i^0$ ,  $\sqrt{z_i}$ ,  $z_i$  and  $z_i \sqrt{z_i}$  contributions of (4.5), are of even orders  $(\mathcal{OT})_i^0$ ,  $(\mathcal{OT})_i^2$ ,  $(\mathcal{OT})_i^4$  and  $(\mathcal{OT})_i^6$  respectively.

The leading order  $\langle \sqrt{z_i} \rangle$  given by

$$\sqrt{\lambda} \sum_{j,k=1}^N \langle \mathcal{O}^{ij} \mathcal{T}_j \mathcal{O}^{ik} \mathcal{T}_k \rangle_{\varepsilon, \Theta} = \sqrt{\lambda} \left\langle \sum_{j=1}^N a_{ij}^2 (\dots \Theta_{lm} \dots) \right\rangle_{\Theta} \mathcal{T}_j^2 = \frac{\sqrt{\lambda}}{N} D C_{2f} \mathbf{1}_{3 \times 3}, \quad (4.6)$$

where  $C_{2f}$  is the quadratic Casimir operator eigenvalue on the fundamental representation,  $C_{2f} = C_F = 4/3$ .  $\mathbf{1}_{3 \times 3}$  is  $3 \times 3$  identity matrix.

The sub-leading order is then,

$$\langle z_i \rangle = \left( \frac{\sqrt{\lambda}}{N} \right)^2 \left( (D C_{2f})^2 + (D C_{3f}) \right) \mathbf{1}_{3 \times 3}, \quad (4.7)$$

where we see the cubic Casimir operator,  $C_{3f}$ , with fundamental representation,

$$\sum_{a,b,c=1}^{N_c^2-1} d_{abc} t^a t^b t^c \equiv C_{3f} \mathbf{1}_{3 \times 3}. \quad (4.8)$$

In Young Tableaus parameters  $p, q$ , we have

$$C_3(p, q) = \frac{1}{18} (p - q)(2p + q + 3)(2q + p + 3). \quad (4.9)$$

Hence, in the  $SU(3)$  fundamental representation,

$$C_{3f} = C_3(1, 0) = \frac{10}{9}. \quad (4.10)$$

. And in the adjoint representation,

$$C_{3a} = C_3(1, 1) = 0. \quad (4.11)$$

The next to sub-leading order  $z_i \sqrt{z_i}$  is given by a combination of  $C_2$ 's and  $C_3$ 's,

$$\langle z_i \sqrt{z_i} \rangle = \left( \frac{\sqrt{\lambda}}{N} \right)^3 \left( [2 + (\frac{5}{6})^2] (DC_{2f})^2 + (DC_{2f})(DC_{3f}) + 3(DC_{3f}) \right) \mathbf{1}_{3 \times 3}. \quad (4.12)$$

It is now clear that  $C_3$  in addition to  $C_2$  will be important in any non-perturbative fermionic Green's function and related processes [34, 35].

# Chapter 5

## Schwinger Action Principle and Generating Functional

### 5.1 Schwinger Action Principle

We begin by writing down the Schwinger's Action Principle [58] for the probability amplitude  $\langle a, t_2 | a', t_1 \rangle$ ,

$$\delta \langle a, t_2 | a', t_1 \rangle = i \langle a, t_2 | \delta W | a', t_1 \rangle \quad (5.1)$$

where  $a$  denotes all appropriate set of eigenvalues, discrete or continuous, that characterize the system at time  $t$ .  $\delta W$  denotes variations in the parametric, end-point, and parameters which the Lagrangian itself may depend on. We assume the property of reality

$$\langle a, t_2 | a', t_1 \rangle \cdot = \langle a', t_1 | a, t_2 \rangle \quad (5.2)$$

and closure

$$\sum_n \langle a, t_2 | n', t \rangle \langle n', t | a', t_1 \rangle = \langle a, t_2 | a', t_1 \rangle \quad (5.3)$$

The unitary operator  $U$  acting on a state vector  $|a, t\rangle$  corresponds to infinitesimal

transformation is

$$\begin{aligned}\delta|a, t\rangle &= -iG(t)|a, t\rangle \\ \delta\langle a, t| &= +i\langle a, t|G(t),\end{aligned}\tag{5.4}$$

where  $G$  is defined by the infinitesimal operator  $\delta(U - 1) = -iG$ . Then combining Eq. 5.1 and Eq. 5.4 gives

$$\delta W = G(t_2) - G(t_1)\tag{5.5}$$

and with total variation  $\delta Q = \delta_0 Q + \delta t \cdot dQ/dt$  giving  $\delta W = Q \cdot P - \delta t \cdot H_{21}$  with  $P = \partial L \partial(dQ/dt)$  and  $H = [dQ/dt] \cdot \partial L / \partial(dQ/dt) - L$ . The quantities  $P$  and  $H$  are coefficients of end-point coordinates or time-variations are precisely the usual definition of momentum and hamiltonian.

Under variations in  $\delta Q$ , we obtain

$$G(t) = P\delta Q - H\delta t\tag{5.6}$$

as the infinitesimal unitary operator for transformations appropriate to coordinate changes and to time translations. It is important to point out that the fundamental statement of quantum physics is a consequence of above derivations. To see this, we choose an arbitrary operator  $O$  and write  $O' = U \cdot OU^\dagger$ , where  $U^\dagger$  is Hermitian adjoint of  $U$ . From Eq. 5.4, we see that variation  $\delta Q$  can be written as  $\delta Q = i[O, G]$ . If we choose, as an example,  $O = Q$ , the generator  $G$  is given by Eq. 5.6 is

$$G = P \delta Q.\tag{5.7}$$

To satisfy relation  $\delta Q = i[P\delta Q, Q]$ , we must adopt

$$[O, P] = i\tag{5.8}$$

where, adjusting for the correct units,  $h/2\pi$ , then the right hand side of the total

variation of  $W$

$$\delta W = \int dt \cdot \delta Q_0 \cdot \left( \frac{\partial L}{\partial Q} - \frac{d}{dt} \left[ \frac{\partial L}{\partial (dQ/dt)} \right] \right) + \left( \delta Q_0 \cdot \left[ \frac{\partial L}{\partial (dQ/dt)} \right] + \delta t \cdot L \right)_{21} \quad (5.9)$$

multiplies Eq. 5.8. As the traditional Action Principle asserts that only terms that depends on the end-time quantities are non-zero, the first term on the RHS of Eq. 5.9 is zero. So, it is from Schwinger's Action Principle that we arrive at the fundamental state of quantum physics, with the expression of the uncertainty principle restricting possible measurements of  $\delta Q$  and  $\delta P$  in a system.

In the vacuum having source field  $j$ , the probability amplitude to find the system at a time  $t_2$  with known vacuum state at  $t_1$  is

$$\langle 0, t_2 | 0, t_1 \rangle_j \quad (5.10)$$

This is the quantity central to all formal functional descriptions. The Action Principle, Eq. 5.1 gives an immediate answer for explicit form of  $j$  dependence.

$$\frac{\delta}{\delta j(x)} \langle 0, t_2 | 0, t_1 \rangle_j = i \langle 0, t_2 | \frac{\delta}{\delta j(x)} W_{2,1} | 0, t_1 \rangle_j \quad (5.11)$$

The coefficients of the implicit variations vanishes for the  $j$  dependence on operators  $A(x)$  because of Euler equations. We then have

$$\frac{\delta}{\delta j(x)} \langle 0, t_2 | 0, t_1 \rangle_j = \langle 0, t_2 | A(x) | 0, t_1 \rangle_j \quad (5.12)$$

and  $n_{th}$  derivative is, with ordered bracket,

$$\left( \frac{1}{n} \right)^n \left[ \frac{\delta}{\delta j(x_1)} \right] \dots \left[ \frac{\delta}{\delta j(x_n)} \right] \langle 0, t_2 | 0, t_1 \rangle_j = \langle 0, t_2 | (A(x_1) \dots A(x_n))_+ | 0, t_1 \rangle_j \quad (5.13)$$

To construct the coefficient of the  $n_{th}$  power of  $j$  in a Taylor expansion, we set  $j = 0$  and obtain

$$\langle 0, t_2 | 0, t_1 \rangle_j = \langle 0, t_2 | (\exp[i \int d^4x j(x) A(x)])_+ | 0, t_1 \rangle \quad (5.14)$$

We introduce the unitary operator  $t^{21}[j] = (\exp[i \int_{t_1}^{t_2} d^4x j(x) A(x)])_+$ . By taking the limit  $t_2 \rightarrow \infty$  and  $t_1 \rightarrow \infty$ , the vacuum expectation value of Eq. 5.14 defines the Generating Functional, GF,  $\mathcal{Z}[j]$ , or

$$\mathcal{Z}[j] = \langle 0, t_2 | 0, t_1 \rangle_j = \lim_{t_1 \rightarrow \infty, t_2 \rightarrow \infty} \langle 0, t_2 | (\exp[i \int_{t_1}^{t_2} d^4x j(x) A(x)])_+ | 0, t_1 \rangle. \quad (5.15)$$

A formal functional solution for Eq. 5.10,  $\langle 0, t_2 | 0, t_1 \rangle_j$  can be obtained by writing down the differential equation

$$\begin{aligned} -i K_x \left[ \frac{\delta}{\delta j(x)} \right] \langle 0, t_2 | 0, t_1 \rangle_j &= \langle 0, t_2 | (j(x) - ng[A(x)]^{n-1}) | 0, t_1 \rangle_j \\ &= \left( j(x) - ng \left( \frac{1}{i} \right)^{n-1} \left[ \frac{\delta}{\delta j(x)} \right]^{n-1} \right) \langle 0, t_2 | 0, t_1 \rangle_j \end{aligned} \quad (5.16)$$

where Euler equation has been used again to result in only explicit  $A(x)$  dependences for  $j$ . Setting  $g = 0$ , we have

$$K_x \left[ \frac{\delta}{\delta j(x)} \right] \langle 0, t_2 | 0, t_1 \rangle_j^{g=0} = ij(x) \langle 0, t_2 | 0, t_1 \rangle_j^{g=0} \quad (5.17)$$

whose solution is

$$\langle 0, t_2 | 0, t_1 \rangle_j^0 = \exp \left[ \frac{i}{2} \int d^4x \int d^4y j(x) \Delta_c(x - y; m^2) j(y) \right] \quad (5.18)$$

where the integration is over all spatial points with all  $t$  between  $t_1$  and  $t_2$ .

If we return to the Action Principle, we can construct a solution to the full Eq. 5.17. Considering variations in the coupling  $g \rightarrow g + dg$ ,

$$\frac{\delta}{\delta g} \langle 0, t_2 | 0, t_1 \rangle_j = -i \langle 0, t_2 | \int_{t_1}^{t_2} d^4x [A(x)]^n | 0, t_1 \rangle_j, \quad (5.19)$$

giving

$$\frac{\delta}{\delta g} \langle 0, t_2 | 0, t_1 \rangle_j = -i \int_{t_1}^{t_2} d^4x \left[ \frac{1}{i} \frac{\delta}{\delta j(x)} \right]^n \langle 0, t_2 | 0, t_1 \rangle_j \quad (5.20)$$

with solution

$$\langle 0, t_2 | 0, t_1 \rangle_j = \exp \left\{ -ig \int_{t_1}^{t_2} d^4x \left[ \frac{1}{i} \frac{\delta}{\delta j(x)} \right]^n \right\} \langle 0, t_2 | 0, t_1 \rangle_j^0 \quad (5.21)$$

or

$$\langle 0, t_2 | 0, t_1 \rangle_j = \exp \left\{ i \int_{t_1}^{t_2} d^4x \mathcal{L}' \left\{ \frac{1}{i} \frac{\delta}{\delta j(x)} \right\}^n \right\} \langle 0, t_2 | 0, t_1 \rangle_j^0 \quad (5.22)$$

The generalized form is then the Generating Functional,

$$\mathcal{Z}^{(0)}[j] = \langle 0, \infty | 0, -\infty \rangle_{j_\mu}^{g=0} = \exp \left[ \frac{i}{2} \int j_\mu D_{c,\mu\nu} j_\nu \right], \quad (5.23)$$

where  $D_{c,\mu\nu}(x - y) = \delta_{\mu\nu} \Delta_c(x - y, m)|_{m \rightarrow 0}$  is the free photon propagator in the Feynman gauge. The GF for free fermions is written with the addition of Grassmann sources,  $\eta_\alpha, \bar{\eta}_\beta$ .

$$\mathcal{Z}^{(0)}[\bar{\eta}, \eta] = \langle 0, \infty | 0, -\infty \rangle_{\nu, \bar{\nu}}^0 = \exp \left[ i \int \bar{\eta} S_c \eta \right] \quad (5.24)$$

As in Eq. 5.14, we get GF for free fermions as

$$\mathcal{Z}^{(0)}[\bar{\eta}, \eta] = \langle 0 | \left( \exp \left[ i \int [\bar{\eta} \psi + \bar{\psi} \eta] \right] \right)_+ | 0 \rangle \quad (5.25)$$

where Grassmann  $\eta_\alpha, \bar{\eta}_\beta$  anticommute with each other and with all free fermion fields  $\psi_\alpha^{(0)}, \bar{\psi}_\beta^{(0)}$ .

The full GF with  $j, \eta$  and  $\bar{\eta}$  is then, from Eq. 5.22, Eq. 5.24 and Eq. 5.25,

$$\begin{aligned} \mathcal{Z}[j, \bar{\eta}, \eta] &= \frac{1}{\langle 0, +\infty | 0, \infty \rangle_{j=\bar{\eta}=\eta=0}} \cdot \exp \left[ -i \int \frac{\delta}{\delta \eta} \left( -g \gamma \cdot \frac{\delta}{\delta j} \right) \frac{\delta}{\delta \bar{\eta}} \right] \cdot \mathcal{Z}^{(0)}[j] \cdot \mathcal{Z}^{(0)}[\bar{\eta}, \eta], \\ &= \exp \left[ -i \int \frac{\delta}{\delta \eta} \left( -g \gamma \cdot \frac{\delta}{\delta j} \right) \frac{\delta}{\delta \bar{\eta}} \right] \cdot \exp \left[ \frac{i}{2} \int j_\mu D_{c,\mu\nu} j_\nu \right] \cdot \exp \left[ i \int [\bar{\eta} \psi + \bar{\psi} \eta] \right]. \end{aligned} \quad (5.26)$$

The QCD Lagrangian is

$$\mathcal{L}_{QCD} = \frac{1}{4} \mathbf{F}_{\mu\nu}^a \mathbf{F}_{\mu\nu}^a - \bar{\psi} \cdot [m + \gamma_\mu (\partial_\mu - ig A_\mu^a \lambda^a)] \cdot \psi, \quad (5.27)$$

where  $\mathbf{F}_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + gf^{abc} A_\mu^b A_\nu^c \equiv \mathbf{f}_{\mu\nu}^a + gf^{abc} A_\mu^b A_\nu^c$ .

Rearranging the Lagrangian [26, 29, 25, 31], we use,

$$\begin{aligned} -\frac{1}{4} \int F^2 &= -\frac{1}{4} \int f^2 - \frac{1}{4} \int [F^2 - f^2] = -\frac{1}{4} \int f^2 + \int \mathcal{L}'[A] \\ \mathbf{f}_{\mu\nu}^a &= \partial_\mu A_\nu^a - \partial_\nu A_\mu^a \\ \mathcal{L}'[A] &= -\frac{1}{4} (2\mathbf{f}_{\mu\nu}^a + gf^{abc} A_\mu^b A_\nu^c)(gf^{abc} A_\mu^b A_\nu^c) \end{aligned} \quad (5.28)$$

After integration by parts, we obtain

$$-\frac{1}{4} \int \mathbf{F}^2 = -\frac{1}{2} \int A_\mu^a (-\partial^2) A_\mu^a + \frac{1}{2} \int (\partial_\mu A_\mu^a)^2 + \int \mathcal{L}'[A] \quad (5.29)$$

To select a particular relativistic gauge, we multiply the term  $\frac{1}{2} \int (\partial_\mu A_\mu^a)^2$  in Eq. 5.29 by  $\lambda$ . We include this term as part of the interaction and obtain

$$\mathcal{Z}_{QCD}^{(\zeta)}[j] = \mathcal{N} \exp[i \int \mathcal{L}'[\frac{1}{i} \frac{\delta}{\delta j}]] \cdot \exp[\frac{i}{2} \lambda \int \frac{\delta}{\delta j_\mu} \partial_\mu \partial_\nu \frac{\delta}{\delta j_\nu}] \cdot \exp[\frac{i}{2} \int j \cdot D_c^{(0)} \cdot j], \quad (5.30)$$

or

$$\mathcal{Z}^{(\zeta)}[j] = \mathcal{N} \exp[i \int \mathcal{L}'[\frac{1}{i} \frac{\delta}{\delta j}]] \cdot \exp[\frac{i}{2} \int j \cdot D_c^{(\zeta)} \cdot j]. \quad (5.31)$$

Here, we have neglected the fermion/quark variables and will reinsert at the end.

Replacing  $\mathcal{L}'$  from Eq. 5.22 gives us,

$$\begin{aligned} \mathcal{Z}_{QCD}^{(\zeta)}[j] &= \mathcal{N} \exp[-\frac{i}{4} \int F^2 - \frac{i}{2} (1 - \lambda) \int (\partial_\mu A_\mu^a)^2 + \frac{i}{2} \int A_\mu^a (-\partial^2) A_\mu^a] \Big|_{A \rightarrow \frac{1}{i} \frac{\delta}{\delta j}} \\ &\quad \cdot \exp[\frac{i}{2} \int j \cdot D_c^{(0)} \cdot j]. \end{aligned} \quad (5.32)$$

The choice of  $\lambda = 1$  can now be made. An important consequence is that the term  $\exp[\frac{i}{2} \int A_\mu^a (-\partial^2) A_\mu^a] \Big|_{A \rightarrow \frac{1}{i} \frac{\delta}{\delta j}}$  effectively removes all factors of  $\exp[\frac{i}{2} \int j \cdot D_c^{(0)} \cdot j]$ , thereby gluons are treated, effectively as ghost fields and gluons themselves are never measurable by themselves. The result is the QCD Generating Functional, after reinserting

the fermion/quark variables,

$$\mathcal{Z}_{QCD}[j, \bar{\eta}, \eta] = \mathcal{N} e^{-\frac{i}{2} \int \frac{\delta}{\delta A} \cdot D_A^{(0)} \cdot \frac{\delta}{\delta A}} \cdot e^{-\frac{i}{4} \int \mathbf{F}^2 + \frac{i}{2} \int A \cdot (-\partial^2) \cdot A} \cdot e^{i \int \bar{\eta} \cdot G_c[A] \cdot \eta + L[A]} \Big|_{A=\int D_c^{(0)} \cdot j} \quad (5.33)$$

The quark variables,  $G[A]$  and  $L[A]$  represents the quark line and quark loop respectively [21, 22]. We shall examine them more closely in next section.

## 5.2 Schwinger Generating Functional

From last section, we started with the Schwinger Generating Functional, GF, for QCD, with gluon operators in an Arbitrary, relativistic, gauge. The GF is rearranged in terms of a "Reciprocity Relation" under a "Gaussian Linkage Operation",  $\exp[-\frac{i}{2} \int \frac{\delta}{\delta A} \cdot D_A^{(0)}]$ . The GF now depends upon two functionals of  $A$ ,

$$\mathcal{Z}_{QCD}[j, \bar{\eta}, \eta] = \mathcal{N} e^{-\frac{1}{2} \int \frac{\delta}{\delta A} \cdot D_c^{(0)} \cdot \frac{\delta}{\delta A}} \cdot e^{-\frac{i}{4} \int \mathbf{F}^2 + \frac{i}{2} \int A \cdot (-\partial^2) \cdot A} \cdot e^{i \int \bar{\eta} \cdot \mathbf{G}_c[A] \cdot \eta + \mathbf{L}[A]} \Big|_{A=\int \mathbf{D}_c^{(0)} \cdot j} \quad (5.34)$$

where the quark line,  $\mathbf{G}_c[x, y | \mathbf{A}] = [m + \gamma \cdot (\delta - igA\tau)]^{-1}$  and virtual quark loop,  $\mathbf{L}[\mathbf{A}] = \ln[1 - i\gamma \mathbf{A} \tau_c[0]]$ .

The GF can now can be rearranged into gauge-invariant form. This was overlooked for decades [26, 24].

Now combine with Fradkin expressions for the quark line,  $\mathbf{G}_c[A]$ , and quark loop,  $\mathbf{L}[A]$ . Efimov S. Fradkin gave expressions for  $\mathbf{G}_c[A]$  and  $\mathbf{L}[A]$  in gaussian form [21, 22]. These are exact.

Fradkin's representation for the quark line,  $\mathbf{G}[A]$  is given by

$$\begin{aligned}
& \mathbf{G}_c(x, y|A) \\
= & i \int_0^\infty ds e^{-ism^2} e^{-\frac{1}{2}Tr\ln(2h)} \int d[u] e^{\frac{i}{4} \int_0^s ds' [u'(s')]^2} \delta^{(4)}(x - y + u(s)) \\
& \times \left[ m - \gamma_\mu \frac{\delta}{\delta u'_\mu(s)} \right] \mathcal{N}_\Omega \mathcal{N}_\Phi \int d[\alpha] \int d[\Xi] \int d[\Omega] \int d[\Phi] \left( e^{i \int_0^s ds' [\alpha^a(s') - i\sigma_{\mu\nu} \Xi_{\mu\nu}^a(s')] \tau^a} \right)_+ \\
& \times e^{-i \int ds' \Omega^a(s') \alpha^a(s') - i \int ds' \Phi_{\mu\nu}^a(s') \Xi_{\mu\nu}^a(s')} \\
& \times e^{-ig \int ds' u'_\mu(s') \Omega^a(s') A_\mu^a(y - u(s')) + ig \int ds' \Phi_{\mu\nu}^a(s') \mathbf{F}_{\mu\nu}^a(y - u(s'))}, 
\end{aligned} \tag{5.35}$$

while the Fradkin's representation for the quark loop,  $\mathbf{L}[A]$  is given by

$$\begin{aligned}
\mathbf{L}[A] = & -\frac{1}{2} \int_0^\infty \frac{ds}{s} e^{-ism^2} e^{-\frac{1}{2}Tr\ln(2h)} \\
& \times \mathcal{N}_\Omega \mathcal{N}_\Phi \int d^4x \int d[\alpha] \int d[\Omega] \int d[\Xi] \int d[\Phi] \\
& \times \int d[v] \delta^{(4)}(v(s)) e^{\frac{i}{4} \int_0^s ds' [v'(s')]^2} \\
& \times e^{-i \int ds' \Omega^a(s') \alpha^a(s') - i \int ds' \Phi_{\mu\nu}^a(s') \Xi_{\mu\nu}^a(s')} \cdot Tr \left( e^{i \int_0^s ds' [\alpha^a(s') - i\sigma_{\mu\nu} \Xi_{\mu\nu}^a(s')] \tau^a} \right)_+ \\
& \times e^{-ig \int_0^s ds' v'_\mu(s') \Omega^a(s') A_\mu^a(x - v(s')) - 2ig \int d^4z (\partial_\nu \Phi_{\nu\mu}^a(z)) A_\mu^a(z)} \\
& \times e^{+ig^2 \int ds' f^{abc} \Phi_{\mu\nu}^a(s') A_\mu^b(x - v(s')) A_\nu^c(x - v(s'))} \\
& - \{g = 0\},
\end{aligned} \tag{5.36}$$

See Appendix A for details on Fradkin's variables. The  $\mathbf{F}^2$  in the GF Eq. 5.34 can be rewritten using Halpern's half century old expression [38, 39],

$$e^{-\frac{i}{4} \int \mathbf{F}^2} = N \int d[\chi] e^{\frac{i}{4} \int \chi^2 + \frac{i}{2} \int F \cdot \chi}, \tag{5.37}$$

where  $\chi_{\mu\nu}^a = -\chi_{\nu\mu}^a$ . With the  $\exp[-\frac{i}{4} \int \mathbf{F}^2]$  in the GF in Gaussian form, under  $\chi$  fields, the relevant Gaussian Functional operations can be performed exactly. This corresponds to the summation of all Feynman graphs of gluons exchanged between quarks.

Then the explicit cancellation of all the gauge-dependent gluon propagators is

obtained as will be shown in next Chapter, Section 6.1.

### 5.3 The importance of non-perturbative solutions in QCD

Amongst the reasons that give perturbative QCD difficulties is because there are ,in effect, two coupling constants, Quarks and gluons,  $g_1$  and  $g_2$  respectively. Expansion around  $g_2 = 0$  will not be sensible when we are looking at  $\frac{g_1^2}{g_2}$  terms.

# Chapter 6

## Explicit Gauge Invariance

### 6.1 Gauge Cancellations

A rearrangement can now be made to formally insure gauge-invariance, even though the GF still apparently contains gauge-dependent gluon propagators.

$$\mathcal{Z}_{QCD}[j, \bar{\eta}, \eta] = \mathcal{N} e^{-\frac{1}{2} \int \frac{\delta}{\delta A} \cdot D_c^{(0)} \cdot \frac{\delta}{\delta A}} \cdot e^{-\frac{i}{4} \int \mathbf{F}^2 + \frac{i}{2} \int A \cdot (-\partial^2) \cdot A} \cdot e^{i \int \bar{\eta} \cdot \mathbf{G}_c[A] \cdot \eta + \mathbf{L}[A]} \Big|_{A=\int \mathbf{D}_c^{(0)} \cdot j} \quad (6.1)$$

Gives 2n-point functions:

$$= \mathcal{N} \int d[\chi] e^{\frac{i}{4} \int \chi^2} e^{\mathfrak{D}_A^{(0)}} e^{\frac{i}{2} \int \chi \cdot \mathbf{F} + \frac{i}{2} \int A \cdot (D_c^{(0)})^{-1} \cdot A} G_c(1|gA) G_c(2|gA) e^{L[A]} \Big|_{A=0} \quad (6.2)$$

Then,

$$\begin{aligned} e^{\mathfrak{D}_A} F_1[A] &= \exp \left[ \frac{i}{2} \int \bar{Q} \cdot D_c^{(0)} \cdot (1 - \bar{K} \cdot D_c^{(0)})^{-1} \cdot \bar{Q} - \frac{1}{2} \text{Tr} \ln(1 - D_c \cdot \tilde{K}) \right] \\ &\cdot \exp \left[ \frac{1}{2} \int A \cdot \bar{K} \cdot (1 - D_c^{(0)} \cdot \bar{K})^{-1} \cdot A + i \int \bar{Q} \cdot (q - \bar{K} \cdot D_c^{(0)})^{-1} \right] \end{aligned} \quad (6.3)$$

where

$$\begin{aligned} D_c^{(0)} \cdot (1 - \bar{K} \cdot D_c^{(0)})^{-1} &= D_c^{(0)} \cdot [1 - (\hat{K} + (D_c^{(0)})^{-1}) \cdot D_c^{(0)}]^{-1} \\ &= -(\tilde{K}_{\mu\nu}^{ab} + g f^{abc} \chi_{\mu\nu}^c)^{-1} \\ &= -\hat{\mathbf{K}}^{-1} \end{aligned} \quad (6.4)$$

connects two quarks, forming the basis of our Gluon Bundle.

Remembering that  $\exp[\frac{i}{2} \int \frac{\delta}{\delta A'} \cdot D_c^{(0)} \cdot \frac{\delta}{\delta A'}]$  is the inverse of  $e^{\mathcal{D}_A}$ , we arrive at

$$\begin{aligned} e^{\mathcal{D}_A} F_1[A] F_2[A] &= \exp\left[-\frac{i}{2} \int \bar{Q} \cdot \hat{\mathbf{K}}^{-1} \cdot \bar{Q} + \frac{1}{2} \text{Tr} \ln \hat{\mathbf{K}} + \frac{1}{2} \text{Tr} \ln(-D_c^{(0)})\right] \\ &\quad \cdot \exp\left[\frac{i}{2} \int \frac{\delta}{\delta A'} \cdot \mathbf{D}_c^{(0)} \cdot \frac{\delta}{\delta A'}\right] \\ &\quad \cdot \exp\left[\frac{i}{2} \int \frac{\delta}{\delta A'} \cdot \hat{\mathbf{K}}^{-1} \cdot \frac{\delta}{\delta A'} - \int \bar{Q} \cdot \hat{\mathbf{K}}^{-1} \cdot \frac{\delta}{\delta A'}\right] \\ &\quad \cdot (e^{\mathcal{D}_A} F_2[A']) \end{aligned} \quad (6.5)$$

$$\begin{aligned} e^{\mathcal{D}_A} F_1[A] F_2[A] &= \mathfrak{N} \exp\left[-\frac{i}{2} \int \bar{Q} \cdot \hat{\mathbf{K}}^{-1} \cdot \bar{Q} + \frac{1}{2} \text{Tr} \ln \hat{\mathbf{K}}\right] \\ &\quad \cdot \exp\left[\frac{i}{2} \int \frac{\delta}{\delta A} \cdot \hat{\mathbf{K}}^{-1} \cdot \frac{\delta}{\delta A} - \int \bar{Q} \cdot \hat{\mathbf{K}}^{-1} \cdot \frac{\delta}{\delta A}\right] \\ &\quad \cdot \exp[L[A]] \end{aligned} \quad (6.6)$$

As one sees in equation 6.6, all the explicit gauge dependent propagators cancel. This is gauge invariant by means of gauge-independence. It deserves to be emphasized that Gauge Independence is the strongest form of Gauge Invariance. Feynman had long hoped for this for QED.

The  $-\hat{\mathbf{K}}^{-1}$  above, also written as  $(f \cdot \chi)^{-1}$  represents infinite gluon exchanges summed. This term is the *Gluon Bundle*, GB, exchanged between two quarks as shown in figure 6-1.

Figure 6-1: A *Gluon Bundle*, GB, is the term  $(f \cdot \chi)^{-1}$ , representing the exchange of all gluons summed.

All the gaussian linkage operations can then be carried through exactly, corresponding to the summation of all gluons changed between any pair of quark (and/or anti-quark) lines, and including the cubic and quartic gluon interactions. See figure 6-2.

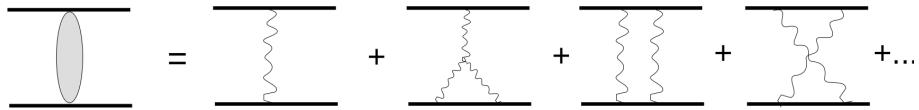

Figure 6-2: A *Gluon Bundle*,  $GB$ , representing the exchange of all gluons summed.

The result is explicit cancellation of all gauge-dependent gluon propagators, with resulting GF exhibiting Manifest Gauge Independence. One also finds a new, exact property of non-perturbative, gauge-invariant QCD, where the space-time coordinates of both ends of a GF are equal, modulo small uncertainties in their transverse coordinates. There is an Effective Locality between interacting quarks, and, changes all the remaining functional integrals into sets of ordinary integrals. One can actually complete these integrals [25, 26, 31]

# Chapter 7

## Effective Locality

### 7.1 Proof of Effective Locality for all quark processes.

Effective Locality is a new property where the coordinates between opposite end points of a Gluon Bundle was the same, modulo transverse quark fluctuations. This property holds true for all quark processes, without approximation and without exception. We prove this below.

In the QCD Generating Functional, we have used

$$e^{-\frac{i}{4} \int F_{\mu\nu}^a F_a^{\mu\nu}} = \mathfrak{N} \int d[\chi] e^{\frac{i}{4} \int \chi_{\mu\nu}^a \chi_a^{\mu\nu} + \frac{i}{2} \int \chi_{\mu\nu}^a F_a^{\mu\nu}} \quad (7.1)$$

and

$$\int d[\chi] = \prod_i \prod_a \prod_{\mu>\nu} \int d\chi_{\mu\nu}^a(\omega_i) \quad (7.2)$$

Each  $\chi$  is divided into  $d^4$  volume that is, not part of a function space but becomes individual minkowski space units[29].

$$p_1 + p_2 = p'_1 +'_2 \quad (7.3)$$

are obtained by pair-wise functional differentiation of the Generating Functional with respect to quark sources  $\eta_\mu^a, \eta_\nu^b$ . Each of these operations bring down a set of Green's

function,  $G_c[A]$ .

$$\mathfrak{N} \int d[\chi] e^{\frac{i}{4} \int \chi^2 e^{\mathfrak{D}_A} e^{\frac{i}{2} \int \chi \mathbf{F} + \frac{i}{2} \int \mathbf{A} (\mathbf{D}_c^\zeta)^{-1} \mathbf{A}}} \times [G_c^I(x_1, y_1 | A) G_C^{II}(x_2, y_2 | A) \frac{e^{L[A]}}{S}]_{A=0} \quad (7.4)$$

In the ordered exponentials definite the  $G_c^{I,II}[A]$ , linear  $A_\mu$  dependencies can be factored out in:

$$(e^{g \int_0^s ds' \sigma \cdot F(y - u(s'))} \cdot e^{-ig \int_0^s ds' u'(s') \cdot A(y - u(s'))})_+ \quad (7.5)$$

and

$$(exp[g \int_0^s ds' \sigma_{\mu\nu} \lambda^a f^{abc} A_\mu^b(z) A_\nu^c(z)])_+ \quad (7.6)$$

where  $z = y - u(s')$ .

For example,

$$(e^{2ig \int_{-\infty}^{+\infty} ds p_\mu A_\mu^a(y + 2sp) \lambda^a})_+ = \int \mathfrak{D}\alpha \delta[\alpha^a(s) - 2gp_\mu A_\mu^a(y + 2sp)] (e^{i \int_{-\infty}^{+\infty} ds \alpha^a(s) \lambda^a})_+ \quad (7.7)$$

The result is then

$$e^{-\frac{i}{2} \int \frac{\delta}{\delta A} \cdot D_c^{(\zeta)} \cdot \frac{\delta}{\delta A}} \cdot e^{+\frac{i}{2} \int A \cdot \bar{K} \cdot A + i \int \bar{Q} \cdot A} \cdot e^{L[A]} \quad (7.8)$$

where

$$\bar{K}_{\mu\nu}^{ab} = K_{\mu\nu}^{ab} + [gf^{abc} \chi_{\mu\nu}^c + (D_c^{(\zeta)})^{-1}]_{\mu\nu}^{ab} \quad (7.9)$$

and

$$\bar{Q}_\mu^a = -\partial_\nu \chi_{\mu\nu}^a + Q_\mu^a = -\partial_\nu \chi_{\mu\nu}^a + g[R_{I\mu}^a + R_{II\mu}^a] \quad (7.10)$$

The functional identity

$$e^{\mathfrak{D}_A} \cdot (F_I[A]F_{II}[A]) = (e^{\overleftrightarrow{\mathfrak{D}}_A} \cdot F_I[A]) \cdot e^D \cdot (e^{\mathfrak{D}_{A'}} \cdot F_{II}[A'])_{A'=A} \quad (7.11)$$

is required with the cross-linkage operator

$$\overleftrightarrow{\mathfrak{D}} = -i \int \frac{\overleftrightarrow{\delta}}{\delta A} \cdot D_c^{(\zeta)} \cdot \frac{\overleftrightarrow{\delta}}{\delta A'}, \quad (7.12)$$

As before, all correlation functions does not have  $D_c^\zeta$  dependence, whereas  $\hat{K} = K + g(f \cdot \chi)$  connects all quark lines and quark loops. Further, this connection by  $K$  is "effectively local" from

$$\langle x | \hat{K}^{-1} | y \rangle = \hat{K}^{-1}(x) \delta^{(4)}(x - y) \quad (7.13)$$

A Gluon Bundle reduces coordinates at each end to depend only on the simple combination of  $y$  and Fradkin's variables  $u(s')$  in a specific, for example,  $y - u(s')$ , local way.

Gluon propagators  $D_c(w - z)$  in QCD quark/(anti)quark amplitudes are replaced by contact type interaction term  $\hat{K}^{-1}(w) \times \delta^{(4)}(w - z)$ .

For example, in the Bloch-Nordsieck approximation where

$$\begin{aligned} \langle p | G_c^{BN}[A] | y \rangle &= e^{-ip \cdot y} \cdot i \int_0^\infty ds e^{-is(m^2 + p^2)} m - i\gamma_\mu [p_\mu - gA_\mu^a (+2sp)\lambda^a] \\ &\times (\exp\{g \int_0^s ds' \sigma^{\mu\nu} F_{\mu\nu}^a(y + 2s'p)\lambda^a\} \cdot \exp\{+2ig \int_0^s ds' [p^\mu A_\mu^a(y + 2s'p)\lambda^a]\})_+ \end{aligned} \quad (7.14)$$

leads to

$$\begin{aligned}
& \delta^{(4)}(\omega - y_1 + s_1 p_1) \cdot \delta^{(4)}(\omega - y_2 + s_2 p_2) \\
&= \frac{1}{2pE} \cdot \delta^{(2)}(\vec{y}_{1,\perp} - \vec{y}_{2,\perp}) \cdot \delta(s_1 - s_+) \cdot \delta(s_2 - s_-) \\
&\cdot \delta^{(2)}(\vec{\omega}_\perp - \vec{y}_\perp \cdot \delta(\omega_L - \frac{1}{2}(y_{1,L} + y_{2,L})) \cdot \delta(\omega_0 - y_{1,0} + \frac{E}{p}y_{1,L}).
\end{aligned} \tag{7.15}$$

In the center of mass,

$$\begin{aligned}
\vec{y}_\perp &= \vec{y}_{1,\perp} = -\vec{y}_{2,\perp} \equiv \frac{1}{2}\vec{b}, \\
z_0 &= y_{1,0} - y_{2,0} = 0 \rightarrow s_1 = s_2 \\
y_{1,0} &= \gamma m s_1 \rightarrow s_1 = \frac{y_{1,0}}{(\gamma m)}.
\end{aligned} \tag{7.16}$$

For large  $\gamma$  and any reasonable duration of the scattering,  $s_1 = s_2 \approx 0$ .

$$ig\delta^{(2)}(\vec{b})\Omega_I^a(0)[f \cdot \chi(\omega^{(0)})]^{-1}|_{3,0}^{ab}\Omega_{II}^b(0), \tag{7.17}$$

where  $\omega_\mu^{(0)} = (\vec{y}_\perp, \vec{0}_L; y_0)$  for  $E/p \approx 1$ .

These statements all refer to particles. The longitudinal momenta of quarks can be obtained but the transverse coordinates cannot as required by the introduction of transverse quark imprecision  $\varphi(b)$ .

We now replace  $\delta^{(2)}(\vec{y}_{1,\perp} - \vec{y}_{2,\perp}) = \delta^{(2)}(\vec{b})$  by

$$(2\pi)^2 \int d^2 \vec{k}_\perp e^{i\vec{k}_\perp \cdot \vec{b} - \vec{k}_\perp^2/M^2} = \frac{M^2}{4\pi} \exp\left[-\frac{M^2 \vec{b}^2}{4}\right] \tag{7.18}$$

where  $M \approx$  (total center of mass scattering energy).

$$s_1 = s_2 = s \approx 0$$

$$\begin{aligned}
\omega_\mu &= \omega_\mu^{(0)} \\
\chi &= \chi(\omega_\mu^{(0)})
\end{aligned} \tag{7.19}$$

Hence, we are left with effectively same coordinates at each of the Gluon Bundle [29].

# Chapter 8

## Quarks Transverse Imprecision

### 8.1 Imprecision in Quark's transverse coordinates

An important point is that quarks are never observed individually, and, thus, cannot have fixed coordinates. The correct coordinates for quarks include transverse quark fluctuations. We believe we know how to do this, the work is still underway for understanding quark fluctuations from first principles. What we have done here is to introduce phenomenological transverse fluctuation amplitudes for every quark-gluon vertex, replacing the usual gluon-quark current interaction at the same space-time point

$$\int d^4x \bar{\psi}(x)\gamma_\mu A_\mu^a(x)\tau_a\psi(x) \quad (8.1)$$

by

$$\int d^2x'_\perp \int d^4x \frac{a(x_\perp - x'_\perp)}{a(x_\perp - x'_\perp)} \bar{\psi}(x')\gamma_\mu A_\mu^a(x)\tau_a\psi(x'), \quad (8.2)$$

with  $a(x_\perp - x'_\perp)$  real and symmetric, and  $x'_\mu = (x'_\perp, x_L, x_0)$ . The probability of finding two quarks separated by a transverse (or impact parameter) distance is then  $\varphi(b) = \int \frac{d^2q}{(2\pi)^2} e^{iqb} |\tilde{a}(q)|^2$ .

We chose a deformed gaussian

$$\varphi(b) = \varphi(0)e^{-(\mu b)^2 + \xi} \quad (8.3)$$

with deformation parameter  $\xi$  real and small. A straight forward calculation yields, for small  $\xi$ ,

$$V(r) \approx \xi \mu (\mu r)^{1+\xi} \quad (8.4)$$

. Perhaps it is important to emphasize again that all asymptotic quark states are hadronic bound states of quarks; and for such a bound state we can specify longitudinal and time coordinates, but not transverse coordinates since they are always fluctuating. The conventional "static quark" approximation used in model binding potential calculations in all non-perturbative amplitudes are plagued with divergences. All non-perturbative amplitudes are plagued with absurdities without taking such "transverse imprecision" into account.

Substituting our potential into a Schrodinger binding equation, using the "quantic" approximation then yields  $\mu \sim m_\pi$ , with  $\xi \approx 0.1$ . This is sensible since the maximum fluctuations should be less than  $m_\pi^{-1}$  [27].

Our results encompasses two different lattice calculations,  $V \sim r$  and  $V \sim r \ln(r)$ . All lattice and other model calculations of  $q - \bar{q}$  binding correspond to an amplitude containing only one of the two Casimir  $SU(3)$  invariants,  $C_2$  or  $C_3$ , whereas our amplitude contains both as shown in Section 4, [34, 35]. We used the well-known half century old Eikonal function relation with potential. The minimum bound state energy for the pion shows that most of the pion's mass comes from the gluons forming the GB and relatively little from the quark masses.

# Chapter 9

## QCD renormalization

### 9.1 Cluster Expansion

To obtain all configurations between Gluon Bundles and Quark loops, we use a method suggested by Chemists in molecular configurations. Consider a functional  $L[A]$  which is acted upon by the linkage operator  $\exp[\mathfrak{D}]$ , with  $\mathfrak{D} = -\left(\frac{i}{2}\right) \int \frac{\delta}{\delta A(\mu)} \mathfrak{D}_c(u-v) \frac{\delta}{\delta A(v)}$ . For simplicity, we write

$$\bar{L}[A] = e^{\mathfrak{D}} L[A]. \quad (9.1)$$

To represent  $S[A] = e^{\mathfrak{D}} \cdot e^{L[A]}$ , we convert  $S[A]$  directly to an exponential whose argument is an infinite sum over a set of connected quantities. The representation is

$$S[A] = \exp\left[\sum_{N=1}^{\infty} \frac{Q_N}{N!}\right], \quad (9.2)$$

where the  $Q_N[A]$  are connected functionals, initially defined as

$$\begin{aligned}
 Q_N[A] &= e^{\mathfrak{D}} L^N[A]|_{connected} \\
 &= \prod_{i>j=1}^N e^{\mathfrak{D}_{ij}} \cdot \prod_{i=1}^N e^{\mathfrak{D}_i} L[A_i]|_{connected, A_i=A}, \\
 &= \prod_{i>j}^N e^{\mathfrak{D}_{ij}} \cdot \prod_{i=1}^N \bar{L}[A_i]|_{connected, A_i=A}
 \end{aligned} \tag{9.3}$$

The subscript "connected" indicates that at least one linkage must be retained between any and each pair of  $L[A_k]$  terms. For  $N = 1$ ,  $Q_1[A] = \bar{L}[A]$ . Explicit  $Q_N$  forms are found by using lagrange multiplier  $\lambda$  such that  $L \rightarrow \lambda L$ , then  $Q_N \rightarrow \lambda^N Q_N$ .  $S[A]$  becomes

$$exp\left[\sum_{n=1}^{\infty} \frac{\lambda^n Q_n}{n!}\right] = e^{\mathfrak{D}} \cdot e^{\lambda L} \tag{9.4}$$

or

$$\sum_{n=1}^{\infty} \frac{Q_n}{n!} = \ln[e^{\mathfrak{D}} \cdot e^{\lambda L}] \tag{9.5}$$

Each  $Q_N$  can be obtained by applying  $(\partial/\partial\lambda)^N|_{\lambda=0}$  on above. For example,  $Q_1 = [e^{\mathfrak{D} \cdot L e^{\lambda L}} [e^{\mathfrak{D} \cdot e^{\lambda L}}]]|_{\lambda=0} = e^{\mathfrak{D}} \cdot L = \bar{L}$ . Figure 9-1. For  $Q_4$ , we obtain the following

$$Q_1 = e^{\hat{\mathfrak{D}}_A} L[A] = \bigcirc + \bigcirc \text{---} + \bigcirc \text{---} \bigcirc + \dots = \bar{L}[A]$$

Figure 9-1: Graphical expansion of  $Q_1$

expansion as shown in figure 9-2. The multiplicative factor for each term can be obtained by direct counting or combinatorics [23].

$$\begin{aligned}
 Q_4 = & \bigcirc \text{---} \bigcirc \text{---} \bigcirc \text{---} \bigcirc + 2 \bigcirc \text{---} \bigcirc \text{---} \bigcirc \text{---} \bigcirc + 3 \bigcirc \text{---} \bigcirc \text{---} \bigcirc \text{---} \bigcirc \\
 & + 4 \bigcirc \text{---} \bigcirc \text{---} \bigcirc \text{---} \bigcirc + 4 \bigcirc \text{---} \bigcirc \text{---} \bigcirc \text{---} \bigcirc + 9 \bigcirc \text{---} \bigcirc \text{---} \bigcirc \text{---} \bigcirc + 12 \bigcirc \text{---} \bigcirc \text{---} \bigcirc \text{---} \bigcirc
 \end{aligned}$$

Figure 9-2: Graphical expansion of  $Q_4$

## 9.2 Renormalization

The radiative corrections of QCD enter when there is momentum transfer between one quark and another quark, where momentum transfer passes through intermediate GBs and/or closed quark loops.

We use an exact functional cluster expansion described in Chapter 2.5 of [23]. In our particular choice of renormalization, we choose  $\delta^2 \ell = \kappa$ , where  $\delta$  represent point where GB connects to a quark loop. The quark loop,  $\ell$ , has the expected UV log divergence and  $\kappa$  is a finite positive constant, figure 9-3.

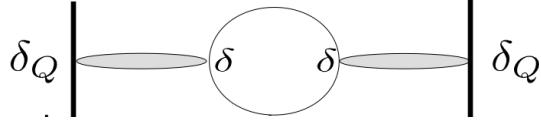

Figure 9-3: We chose a renormalization scheme where two connections of Gluon Bundles,  $\delta$ , multiplied by a quark loop with logarithmic divergence,  $\ell$  are set equal to a finite quantity  $\kappa$ , to be determined by experiments.

With this particular choice of renormalization, only GB chain graphs are non-zero. All other closed loops entering into the functional cluster expansion vanish. In figure 9-2, only the last term will be non-zero. These GB chain graphs form a geometric series which can be summed, and is everywhere finite. See figure 9-4.

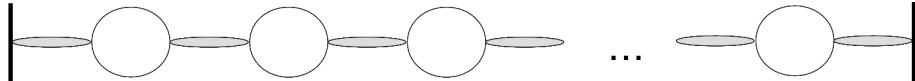

Figure 9-4: We set  $\delta^2 \cdot \ell = \kappa$ , where  $\kappa$  is assumed finite and determined by experiment. This simplifies all possible loop connections with Gluon Bundles to only the straight chains. This is the first attempt at renormalization, and, thus far, compares well with experiments.

The real radiative corrections in QCD are formed from Gluon Bundles and Quark-Antiquark loops. We are in position now to calculate scattering amplitudes between Quark/(anti)Quark processes.

All the basic radiative correction structure of non-perturbative QCD comes from interacting closed-quark-loops with GB's. A single dressed quark has an amplitude

proportional to

$$N \int d[\chi] e^{i\frac{\chi^2}{4}} (\det(gf \cdot \chi)^{-\frac{1}{2}}) e^{\hat{\mathcal{D}}_A} \cdot G_c[A] e^{L[A]}|_{A \rightarrow 0}, \quad (9.6)$$

While two scattering quarks are described by

$$N \int d[\chi] e^{i\frac{\chi^2}{4}} (\det(gf \cdot \chi)^{-\frac{1}{2}}) e^{\hat{\mathcal{D}}_A} G_c^{(1)}[A] G_c^{(2)}[A] e^{L[A]}|_{A \rightarrow 0}, \quad (9.7)$$

where  $\hat{\mathcal{D}}_A = \frac{i}{2} \int \frac{\partial}{\partial A} (gf \cdot \chi)^{-1} \frac{\partial}{\partial A}$ .

### 9.3 Quark self-energy

Every GB exchanged is represented by the linkage operator connecting the two  $G_c[A]$ 's to each other, and the  $G_c[A]$ 's to  $L[A]$ . Explicit calculation shows that all self-energy graphs vanish either by asymmetry of the  $(f \cdot \chi)^{-1}$  color and indices or by explicit loop integration. See Figure 9-5. All self energies of a quark are exactly 0. Of course, we cannot make comments on individual quark masses, the quark line in Figure 9-5 includes its transverse imprecision as discussed in Section 8.1. In other words, realistic quarks must be in bound states.

Non-perturbative QCD turns out to be far simpler than QED.

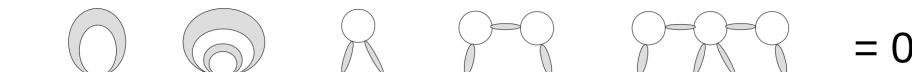

Figure 9-5: All self energy graphs with Gluon Bundles are zero, 0.

# Chapter 10

## Masses and Confinement Scale(s)

### 10.1 QCD confinement scale(s)

In the formulation in 8.1, the confinement mass  $\mu$  appears in the transverse fluctuation probability  $\varphi(b)$ . Values of  $b > 1/\mu$  give negative contributions to any Fourier transform of powers of  $\varphi(b)$ . We shall use a simpler procedure here to obtain an approximate equation for the bound state energy,  $m_{bs}$ .

$$\varphi(b) = \varphi(0) e^{-(\mu b)^{2+\xi}}, \quad (10.1)$$

The transverse fluctuations of the bound quarks inside a bound state particle cannot be larger than the Compton wavelength of that particle. The deformation parameter  $\xi$  in Eq. 10.1 is the origin of quark binding in section 8.1. For a pion,  $b$  is the transverse separation of a  $q - \bar{q}$  pair forming a pion, and  $\mu$  is the mass scale such that transverse fluctuations larger than  $\mu^{-1}$  give little contribution. Deformation parameter  $\xi$  is a small, real and positive number, of the order of 0.1 in a pion [32].

Of note is that the  $G_{34}^{23}$  Meijer function's in section 4.2 mixes partonic variables  $m, \hat{s}$  with Eq 10.1. This is a prediction in Brodsky and company's approach in [49, 11].

The corresponding potential arrived through Eikonal function,  $\chi$  of chapter 2.4, is that of Eq. 8.4,

$$V(r) \simeq \xi \mu (\mu r)^{1+\xi}, \quad (10.2)$$

where  $\mu$  was taken to be on the order of the pion mass,  $m_\pi$ .

For larger bound states,  $\mu$  is that larger particle's mass,  $m_{BS}$ . Deformation parameter is expected to be smaller than  $\xi < \xi_\pi$  used for the pion. In our formulation, 3 quarks bound states have  $xi_{nucleon} \sim 0.1$ . The Fourier transform of  $\varphi(b)$  is then

$$\exp[-\vec{q}^2/4m_p^2], \quad (10.3)$$

where  $m_p$  is the proton's mass. Eq. 10.3 is of the form of momentum space fall-off suggested in recent Brodsky and company's light-front analysis [49, 11].

For a simplified analysis, we replace the  $r_{ij}$  in each of the  $q - \bar{q}$ 's  $V(r)_{ij}$  with  $1/m_\pi$ . We can now write energy of a bound particle,  $E_0$  as,

$$E_0 \rightarrow m_{BS} \simeq n_q m_q + \xi \sum_q m_{BS} \left( \frac{m_{BS}}{m_\pi} \right)^{1+\xi}, \quad (10.4)$$

where  $\sum_q$  represents the number of pairwise  $q$  and/or  $\bar{q}$  interactions. One them obtains

$$m_{BS} \simeq n_q m_q + \frac{n_q(n_q - 1)}{2} m_{BS} \xi \left( \frac{m_{BS}}{m_\pi} \right)^{1+\xi}; \quad (10.5)$$

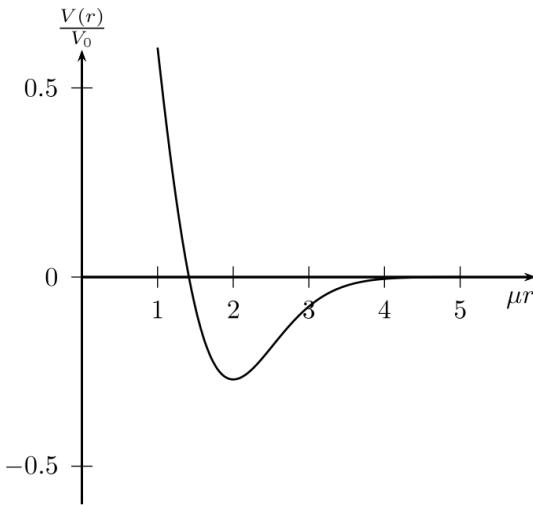

and since  $\xi$  is expected to be  $\ll 1$ , Eq. 10.5 simplifies further to

$$\xi \simeq [1 - \frac{n_q m_q}{m_{BS}}] \cdot \left( \frac{1}{\frac{n_q(n_q - 1)}{2} \left( \frac{m_{BS}}{m_\pi} \right)} \right). \quad (10.6)$$

What we have is that  $\mu$  is mass of the bound state  $m_{BS}$  and must be less than the Compton wavelength of the particle. This in term determines the deformation parameter  $\xi$ . The reverse is also true: if we know  $\xi$ , we can determine  $m_{BS}$ . The mass parameters in later chapter 11 and chapter 12 can be determined if we have  $\xi$ . Some values for bound states have been listed in Table B.1 in Appendix B.

## 10.2 Nuclear physics from QCD

In the same light, nucleon binding is examined. Here is the first (to our knowledge) example of nucleon binding, for a model deuteron, from basic QCD [28]. We have performed a qualitative model, without electrical charge and nucleon spins which can always be added in, to describe the essence of Nuclear Physics. Assuming an average quark for ease of calculation, an attractive potential is obtained [27, 24]. Quark binding takes place for  $r_{ij} \approx m_\pi^{-1}$ , but for nucleon binding that takes place at larger distances. Extraction and regularization of the logarithmic UV divergence loop will

**Fig. 3.** Nucleon potential with  $V_0 = c(\frac{g_A^2}{4\pi})\mu$ .

Figure 10-1: Nucleon nucleon binding is mediated by the exchange of Gluon Bundles supporting one or more closed quark loops. The change in sign is the important factor that enables binding to occur.

contribute two essential features.

1. The loop stretches, so distances larger than  $m_\pi^{-1}$  can easily enter
2. It provides a crucial change of sign for the effective n-n binding potential, figure 10-1, [27].

We expect and hope that nuclear physicists will employ such effective potentials to discuss heavier nuclei. A model deuteron is constructed from first principles in article [28]. See Figure 10-2.

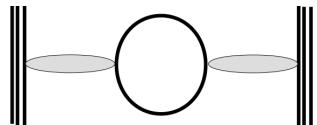

Figure 10-2: Nucleon nucleon binding is mediated by the exchange of Gluon Bundles with a quark loop that is able to stretch to distances greater than that of a pion. The change in sign in the derived potential in Figure 10-1 provides the crucial ingredient for binding to occur.

# Chapter 11

## QCD Scattering Amplitude

### 11.1 Eikonal approximation

The scattering amplitude we obtain from the eikonal is:

$$T_{eikonal}(s, t; g^2) = \frac{is}{2m^2} \int d^2 b e^{iqb} [1 - e^{i\chi_0(s, b)}] \quad (11.1)$$

The relation between  $\tilde{\varphi}(b)$  and the eikonal,  $\chi$  is given by

$$e^{i\chi(s, b)} = \mathfrak{N} \int_0^\infty dR R^3 e^{iR^2/4 + ig\tilde{\varphi}(b)/R} \quad (11.2)$$

if we used our  $R^2 = \sum_a \chi^2$  approximation. The amplitude can be calculated exactly, however, at this stage, we use our intuitive understanding that all the angles in the color space are the same. The  $s$  dependence will be part of our normalization for the  $\delta$  that connects a real physical quark to a gluon bundle, this takes the form  $(m/E)^{2p}$  where  $p$  is to be extract from experiments.

### 11.2 Scattering Amplitude

With our renormalization scheme, and a first rough pass as averaging  $\sum \chi^2$ 's by an average  $R^2$ , we calculate quark/(anti)quark scattering amplitude,  $T$ .

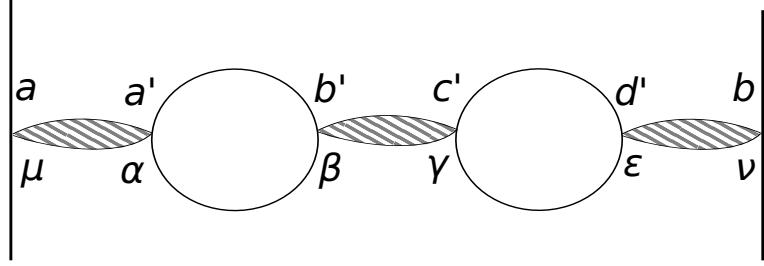

Figure 11-1: Two averaged quarks connected by GB's and two loops.

For ease of presentation, let's calculate a two loop chain graph scattering amplitude,  $T$ , in Fig. 11-1.  $T$  is proportional to

$$\begin{aligned}
 T = & \int_0^s ds_1 u'_\mu(s_1) \Omega_a(s_1) \int_0^{\bar{s}} d\bar{s}_1 \bar{u}'_\nu(\bar{s}_1) \bar{\Omega}_b(\bar{s}_1) \cdot \int_0^t dt_1 v'_\alpha(t_1) \hat{\Omega}_{a'}(t_1) \\
 & \cdot \int_0^t dt_2 v'_\beta(t_2) \hat{\Omega}_{b'}(t_2) \cdot \int_0^{\bar{t}} d\bar{t}_1 \bar{v}'_\gamma \check{\Omega}_{c'}(\bar{t}_1) \cdot \int_0^{\bar{t}} d\bar{t}_2 \bar{v}'_\epsilon(\bar{t}_2) \check{\Omega}_{d'}(\bar{t}_2) \\
 & \cdot \int d^2 y'_\perp \mathfrak{a}(y_\perp - y'_\perp) \cdot \int d^2 \bar{y}'_\perp \mathfrak{a}(\bar{y}_\perp - \bar{y}'_\perp) \cdot \int d^2 x'_\perp \mathfrak{a}(x_\perp - x'_\perp) \\
 & \cdot \int d^2 x''_\perp \mathfrak{a}(x_\perp - x''_\perp) \cdot \int d^2 \bar{x}'_\perp \mathfrak{a}(\bar{x}_\perp - \bar{x}'_\perp) \cdot \int d^2 \bar{x}''_\perp \mathfrak{a}(\bar{x}_\perp - \bar{x}''_\perp) \\
 & \cdot \delta^{(4)}(y' - u(s_1) - x' + v(t_1)) \cdot \delta^{(4)}(x'' - v(t_2) - \bar{x}' + \bar{v}(\bar{t}_1)) \cdot \delta^{(4)}(\bar{x}'' - \bar{v}(\bar{t}_2) - \bar{y}' + \bar{u}(\bar{s}_1)) \\
 & \cdot [f \cdot \chi(y' - u(s_1))]^{-1}|_{\mu\alpha}^{aa'} \cdot [f \cdot \chi(\bar{x}' - \bar{v}(\bar{t}_1))]^{-1}|_{\beta\gamma}^{b'c'} \cdot [f \cdot \chi(\bar{y}' - \bar{u}(\bar{s}_1))]^{-1}|_{\epsilon\nu}^{d'b},
 \end{aligned} \tag{11.3}$$

where the  $\mathfrak{a}(z_\perp - z'_\perp)$  represent the probability amplitudes of each quark to be found at a perpendicular distance  $z'_\perp$  about its average. The probability of an individual GB delivering momentum  $q$  is given by  $\tilde{\varphi}(q) = [\tilde{\mathfrak{a}}(q)]^2$ . The  $\delta$ -functions of Eq. (11.3) shows *Effective Locality*, and  $z'_\mu = (z_0, z_L; z'_\perp)$ , where  $0$  is time-like and  $L$  is longitudinal components. The three  $(f \cdot \chi)^{-1}$ 's are the three GB's in  $T$ . The  $x$  and  $\bar{x}$  are the space-time coordinates of each loop. The  $y$  and  $\bar{y}$  coordinates represent each quark, with corresponding Fradkin functional variables  $u(s')$  and  $u(s')$ .

Now perform the following steps:

1. Suppress the primes in the arguments of each  $(f \cdot \chi)^{-1}$ ; the justification for this step is given in Appendix B of Ref. [30].
2. Assume that  $[f \cdot \chi(\bar{x} - \bar{v}(\bar{t}_1))]^{-1}$  is labeled only by its transverse arguments, an

assumption made for convenience, which is consistent with the final results of this exercise.

3. Write an integral representation for each of the time-like and longitudinal  $\delta$ -functions of Eq. (11.3), thereby introducing the Fourier variables  $q_0, q_L, p_0, p_L, k_0, k_L$ . Assume the two quarks of Fig. 11-1 are scattering at high energy and use the Eikonal Model. This removes the need for an integration over the Fradkin  $u$ - and  $\bar{u}$ -dependence. The result is that the Fourier variables  $q_0, q_L, p_0, p_L, k_0, k_L$  vanish, leaving only transverse  $q_\perp, p_\perp, k_\perp$  dependence.
4. Write Fourier representations for the remaining three transverse delta-functions of Eq. (11.3), and calculate the integrals  $\int d^2y'_\perp \cdot \int d^2\bar{y}'_\perp \cdot \int d^2x'_\perp \cdot \int d^2x''_\perp \cdot \int d^2\bar{x}'_\perp \cdot \int d^2\bar{x}''_\perp$  to obtain factors of  $\tilde{\varphi}(q) \cdot \tilde{\varphi}(p) \cdot \tilde{\varphi}(k)$  where all previous  $z'_\perp$  are effectively replaced by  $z_\perp$ .
5. Calculate  $\int d^2x_\perp \cdot \int d^2\bar{x}_\perp$  and find that  $p_\perp = k_\perp = q_\perp$ , so that there is but one transverse integral,  $\int d^2q_\perp \equiv \int d^2q$  remaining.

The three transverse  $\delta$ -functions multiplying the last line of Eq. (11.3) can be used to re-write the  $[f \cdot \chi(\bar{x} - \bar{v}(t_1))]^{-1}$  term as

$$\begin{aligned} & \left[ f \cdot \chi \left( \frac{1}{2} [x - v(t_2) + \bar{x} - \bar{v}(\bar{t}_1)] \right) \right]^{-1} \\ \Rightarrow & \left[ f \cdot \chi \left( \frac{1}{2} [y - u(s_1) + v(t_1) - v(t_2) - \bar{v}(\bar{t}_1) + \bar{v}(\bar{t}_2) + \bar{y} - \bar{u}(\bar{s}_1)] \right) \right]^{-1}, \end{aligned} \quad (11.4)$$

and, as explained in Ref. [30, 33], in the Center of Mass (CM) of the scattering quarks, with the zero of time chosen as that time when both quarks' longitudinal coordinates are zero, the Eikonal Model effectively replaces  $y - u(s_1)$  by  $y_\perp$ , and  $\bar{y} - \bar{u}(\bar{s}_1)$  by  $\bar{y}_\perp$ . This replaces Eq. (11.4) by

$$\left[ f \cdot \chi \left( \frac{1}{2} [y_\perp + \bar{y}_\perp + \Delta v - \Delta \bar{v}] \right) \right]^{-1}, \quad (11.5)$$

where  $\Delta v = v(t_1) - v(t_2)$ , and  $\Delta \bar{v} = \bar{v}(\bar{t}_1) - \bar{v}(\bar{t}_2)$ . With the CM value of the transverse

vectors  $y_\perp + \bar{y}_\perp = 0$ , Eq. (11.5) reduces to

$$\left[ f \cdot \chi \left( \frac{1}{2} [\Delta v - \Delta \bar{v}] \right) \right]^{-1}. \quad (11.6)$$

The remaining transverse integral over  $d^2 q_\perp$  has

$$e^{iq \cdot [y_\perp - \bar{y}_\perp + \Delta v + \Delta \bar{v}]}, \quad (11.7)$$

in its integrand, where  $y_\perp - \bar{y}_\perp = \vec{b}$  is the impact parameter. The  $(f \cdot \chi)^{-1}$  of Eq. (11.6) must now be included as part of Fradkin's  $v$  and  $\bar{v}$ -integrals. For this, we write a Fourier representation of Eq. (11.6) as

$$\int \frac{d^2 K}{(2\pi)^2} \tilde{\mathcal{F}}(K) e^{i \frac{K}{2} [\Delta v - \Delta \bar{v}]}, \quad (11.8)$$

and note that the UV divergent part of the Fradkin integrals over both loops,  $\int d[v] \cdot \int d[\bar{v}]$ , is proportional to the product

$$\left[ -\lambda \delta_{\alpha\beta} (q + \frac{1}{2} K)^2 \ell \right] \cdot \left[ -\lambda \delta_{\gamma\epsilon} (q - \frac{1}{2} K)^2 \ell \right], \quad \ell = \ln(1/m) \quad (11.9)$$

using our original approximation for the spin dependence of each loop. Note that the color indices of each side of the loop are forced to be identical in the divergent limit of the loop.

Without its  $K$ -dependence, Eq. (11.9) is just given by the product of the two loops'  $q^2$ -factors. That  $K$ -dependence appears in the form of a sum over products of polynomial dependence on  $K$  components, multiplying the transform  $\tilde{\mathcal{F}}$ . We now take the inverse transform with

$$\tilde{\mathcal{F}}(K) = \int d^2 B e^{-i K \cdot B} [f \cdot \chi(B)]^{-1}. \quad (11.10)$$

Each  $K$ -component  $K_\alpha$  can be expressed as a derivative with respect to  $B_\alpha$  of the inverse transform,  $K_\alpha \rightarrow i \frac{\partial}{\partial B_\alpha}$ . An integration-by-parts transforms this and all such derivatives from the polynomial  $K$ -dependence of Eq. (11.9) into one or more deriva-

tives operating upon  $[f \cdot \chi(B)]^{-1}$ . The  $\int d^2K$  can now be immediately, yielding  $\delta^{(2)}(B)$ . The result of all the  $K$ -dependence of Eq. (11.9) is a group of derivatives taken at  $B = 0$ .

We have not yet allowed the small space-time interval of the  $(f \cdot \chi)^{-1}$  of this central GB to vanish, in conjunction with the loop UV divergences becoming infinite. Each of the small space-time volume is completely independent of its neighbors such that the  $\frac{\delta}{\delta B_\alpha}$  operating on them. We are free to define how the limit is to be taken and, we shall, take the simplest case of a "flat" volume without any curvature. Each and every derivative on this flat volume vanishes as  $B \rightarrow 0$ . To put it in another way, any curvature introduces a scale; and there is no relevant scale to adopt.

The contribution of this two-loop chain is then proportional to the product of two groups of  $q$ -factors, one from each loop, separated by the matrix quantity  $[f \cdot \chi(0)]^{-1}|_{\beta\gamma}^{b'c'}$  which we now replace by the simplified expression

$$(-\lambda q^2 \delta_{\alpha\beta})(-\lambda q^2 \delta_{\gamma\epsilon}) \kappa^2. \quad (11.11)$$

This result of the form of Eq. (11.11) will hold for every 'interior' GB of the chain. For example, the three-loop amplitude has four  $(f \cdot \chi)^{-1}$  factors where the central two may both be re-written as

$$\sum_{\beta,c'} [f \cdot \chi(0)]^{-1}|_{\alpha\beta}^{b'c'} \cdot [f \cdot \chi(0)]^{-1}|_{\beta\gamma}^{c'd'}, \quad (11.12)$$

or as  $[f \cdot \chi(0)]^{-2}|_{\alpha\gamma}^{b'd'}$ .

Thus, the result for a chain with  $n$  'interior' GBs yields a term proportional to  $[f \cdot \chi(0)]^n|_{\alpha\gamma}^{b'd'}$  which is inserted between the two 'exterior' GBs,  $[f \cdot \chi(y_\perp)]^{-1}|_{\mu\alpha}^{aa'}$  on the left and  $[f \cdot \chi(\bar{y}_\perp)]^{-1}|_{\epsilon\nu}^{d'b}$  on the right, multiplied by the remaining  $q$ -dependence, and integrated over all transverse  $q$ . With  $a(q^2) = \lambda q^2 \kappa g \tilde{\varphi}(q)$ , all together one has, upon summing over all interior loops which effectively form a geometric series, and

including the amplitude with but one loop,

$$T_{chain} = [f \cdot \chi(y_\perp)]^{-1} \Big|_{\mu\alpha}^{aa'} \cdot ga(q^2) \tilde{\varphi} \times [1 + ia(q^2) [f \cdot \chi(0)]^{-1} - a(q^2)^2 [f \cdot \chi(0)]^{-2} - ia(q^2)^3 [f \cdot \chi(0)]^{-3} + \dots]_{\alpha\beta}^{a'b'} \cdot [f \cdot \chi(\bar{y}_\perp)]^{-1} \Big|_{\beta\nu}^{b'b}, \quad (11.13)$$

or, suppressing matrix indices,

$$T_{chain} = [f \cdot \chi(y_\perp)]^{-1} \cdot ga(q^2) \tilde{\varphi} \left[ \frac{1 + ia(q^2) [f \cdot \chi(0)]^{-1}}{1 + a(q^2)^2 [f \cdot \chi(0)]^{-2}} \right] \cdot [f \cdot \chi(\bar{y}_\perp)]^{-1}. \quad (11.14)$$

Eq. (11.14) can be replaced by

$$T_{chain} = ga(q^2) \tilde{\varphi} [f \cdot \chi(y_\perp)]^{-1} \cdot [f \cdot \chi(0)]^2 \left[ \frac{1 + ia(q^2) [f \cdot \chi(0)]^{-1}}{[f \cdot \chi(0)]^2 + a(q^2)^2} \right] \cdot [f \cdot \chi(\bar{y}_\perp)]^{-1}. \quad (11.15)$$

Since the indices  $\alpha$  and  $\beta$  of  $\chi_{\alpha\beta}^a(0)$  are transverse, all components of  $\chi(0)$  can be chosen as real. With  $f^{abc}$  real,  $[f \cdot \chi(0)]^2$  is positive, and the denominator of Eq. (11.15) is never zero. The  $\chi(0)$  contribution to the amplitude is then proportional to

$$g^2 \int d^2 q e^{iq \cdot \vec{b}} \cdot [f \cdot \chi(y_\perp)]^{-1} \cdot I(q^2, g^2) \cdot [f \cdot \chi(\bar{y}_\perp)]^{-1} \quad (11.16)$$

or

$$g_R^2(q^2) = g^2 I(q^2, g^2) q^2 [\tilde{\varphi}(q)]^2 \lambda \kappa \quad (11.17)$$

with

$$I(q^2, g^2) = \mathcal{N} \int d^4 \chi(0) \det[f \cdot \chi(0)]^{-\frac{1}{2}} e^{\frac{i}{4} \chi(0)^2} \frac{[f \cdot \chi(0)]^2}{[f \cdot \chi(0)]^2 + [\lambda \kappa g q^2 \tilde{\varphi}]^2}, \quad (11.18)$$

since the integral  $\int d^n \chi(0)$  over an odd function of  $[f \cdot \chi(0)]^{-1}$  vanishes.

There is no divergence in the integral of Eq. (11.16) for any value of  $q^2$ . The Fourier transform of this integral corresponds to  $q^2$  dependence in momentum space.

This factor will be present in every interacting quarks processes, and as such, can be considered as the renormalized color-charge dependence of this Model renor-

malization, as the 'renormalized' charge which appears in the scattering of a pair of quarks and/or anti-quarks, at  $q$ -values somewhat different from those obtained from simple one-GB exchange. Integrals over this quantity are then finite by virtue of the exponential cut-off appearing in  $\tilde{\varphi}(q)$ , which is (slightly) less strong than Gaussian, reflecting the basic structure of confinement in this Model of Realistic QCD. This chain-graph Bundle structure will be repeated in all of the correlation functions. The integrations over coordinate components are all finite even if complicated. Methods of Random Matrix theory [34, 31] can be used to evaluate multiple-chain contributions to high-energy hadronic reactions, in particular elastic pp scattering.

For ease of computation, and to demonstrate the origin and appearance of the familiar "diffraction dip" in the  $(\text{momentum-transfer})^2$  region of  $\frac{m_p^2}{2}$ , we adopt two intuitive, qualitative approximations for the exchange of a single GB-loop chain between a pair of scattering quarks, each bound into a different proton. For momentum exchange much smaller than the CM energies, individual proton's quarks interactions are suppressed.

The first approximation is to represent the amplitude of a single chain by its first two terms, as pictured in Fig. 11-2. The second approximation is to evaluate  $\int d^n \chi(0)$  by treating  $\chi^a$  as a vector in color space, with magnitude  $R = \sqrt{\sum_a (\chi^a)^2}$ , greatly simplified by suppressing all of the normalized integrations over such angles, and retaining only the normalized integration over  $R$ . This permits evaluations with

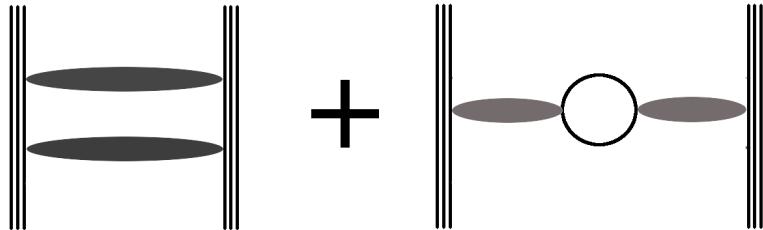

Figure 11-2: First two terms of complete amplitude. A Gluon Bundle term (two bundles because one bundle is anti-symmetric) plus One-Closed-Quark-Loop term

experiments, namely, the differential cross section of elastic proton-proton scattering.

### 11.3 Differential Cross Section

Elastic differential cross section is given by

$$\frac{d\sigma}{dt} = \frac{m^4}{16\pi p^2 E^2} |T_{summed}|^2 \quad (11.19)$$

The amplitude for two Gluon Bundles is

$$\frac{d\sigma}{dt} = k \left[ -12 \frac{\beta_{ext} g^2}{4\pi} \left( \frac{m}{E} \right)^{2p} \left( \frac{m}{E} \right)^{2p} \exp\left(-\frac{3}{8} \frac{x}{m^2}\right) \right]. \quad (11.20)$$

Adding in the one loop amplitude gives

$$\begin{aligned} \frac{d\sigma}{dt} = k & \left[ -12 \frac{\beta_{ext} g^2}{4\pi} \left( \frac{m}{E} \right)^{2p} \left( \frac{m}{E} \right)^{2p} \exp\left(-\frac{3}{8} \frac{x}{m^2}\right) \right. \\ & \left. + 9 \frac{\beta_{ext} g^2}{4\pi} \left( \frac{m}{E} \right)^{2p} 4\pi \lambda \bar{\kappa} \frac{x}{m^2} \exp\left(\frac{-x}{2m^2}\right) \right]^2. \end{aligned} \quad (11.21)$$

The factor  $k$  absorbed all physical constants and converted to the experimental data unit  $mb/GeV$ . The  $\beta$ 's come from the  $\exp[i\beta/4] = \exp[i \sum_a \chi^2/4]$  term and can be calculated exactly with random matrix methods. ( $\beta_{ext}$  connects to physical quarks at the ends of the chain, and  $\beta_{int}$  connects to the virtual interior quark loops.) The factor 12 in front of the Gluon Bundle term represents 12 ways two GB's can be arranged between three and three bound quarks, see Figure 11-2. The factor 9 is the number of ways a single loop chain can connect between three and three bound quarks.

For the infinite loops summed, see Figure 12-9, we calculated the differential cross-

section to be,

$$\begin{aligned}
\frac{d\sigma}{dt} = & k \left[ -12 \frac{\beta_{ext} g^2}{4\pi} \left( \frac{m}{E} \right)^{2p} \left( \frac{m}{E} \right)^{2p} \exp\left(-\frac{3}{8} \frac{x}{m^2}\right) \right. \\
& + 9 \frac{\beta_{ext} g^2}{4\pi} \left( \frac{m}{E} \right)^{2p} 4\pi \lambda \bar{\kappa} \frac{x}{m^2} \exp\left(\frac{-x}{2m^2}\right) \\
& + 9(6 \times 6 \times 2 \times 2)^2 \left( \frac{\beta_{int} g^2}{4\pi} \right) \left( \frac{m}{E} \right)^{2p} (4\pi \lambda \bar{\kappa}) \\
& \left. \left( \frac{1}{2} g \cdot a(x) \tilde{\varphi}(x)^2 \times \left( \frac{\frac{a(x)6-7a(x)^2}{\beta_{int}^2}}{a(x)^8 + \frac{1}{\beta_{int}^4} + \frac{2a(x)^4}{\beta_{int}^2}} \right) \right) \right]^2
\end{aligned} \tag{11.22}$$

where  $a(x) = gx\kappa\tilde{\varphi}(x)$ ,  $x$  is the momentum transfer  $q^2$ ,  $\beta_{ext}$  represents connections to exterior (real) quark line, while  $\beta_{int}$  represents connections to interior quark loops.  $\tilde{\varphi}(x) = \exp[-i(x/m)^{2-\eta}]$  is the fourier transform of our transverse quark imprecision distribution,  $\varphi(b)$  in equation 8.3 where  $\eta$  is the inverse of  $\xi$ . For simplicity, we shall let experiments determine  $\beta$ , while coupling  $g$ , renormalizations  $\kappa$ ,  $p$ , and  $m$  must be extracted from experiments.

# Chapter 12

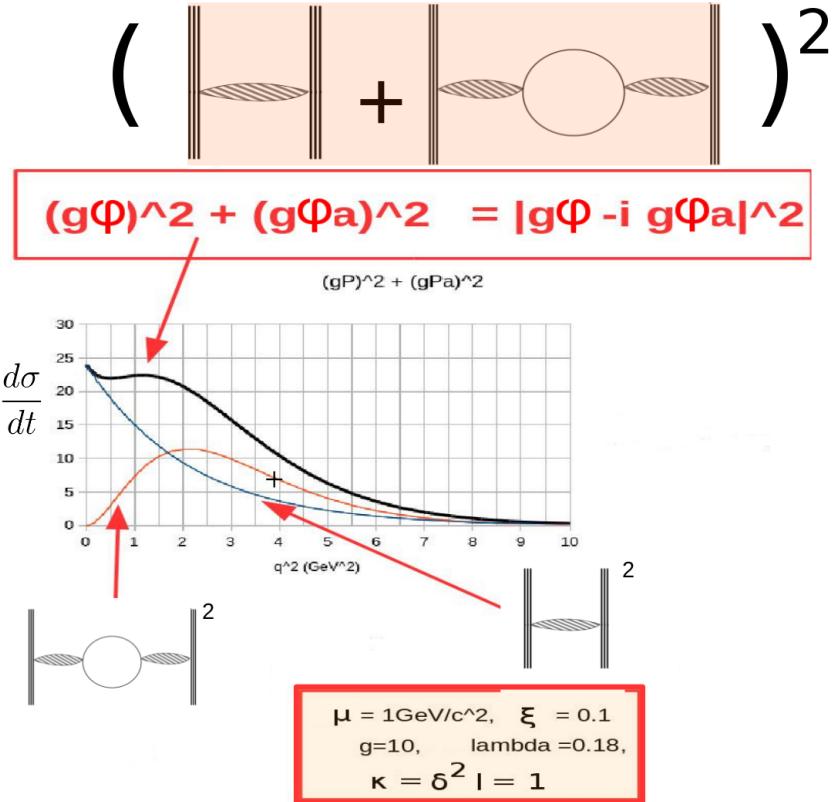

## Comparison with High Energy scattering experiments

### 12.1 Elastic pp-scattering

In high energy hadron scattering, pp-scattering in particular, there has always been a 'diffraction dip' that was difficult to explain and certainly not from first principles. There are form factors, or other methods attempted. For us, we calculate the differential cross section from, intuitively trying a GB exchanged between two hadrons (3 quarks that are not breaking up) and a GB-virtual quark loop-GB configuration. Just to get an intuitive understanding. Low and behold, we have a diffraction dip as seen in experiments. It comes from quark-GB-quark and quark-GB-virtualquarkloop-GB-quark, Figure 12-1 and Figure 12-2, [33].

The contribution from purely GB's exchanged between two nucleons provide an amplitude with exponential fall off, while the one-loop-term provides a rising function, figure 12-1, that, when both combined explains the diffraction dip. The exact form that includes infinite sum of all chain loops are currently underway. We expect favorable comparison with the experimental measurements [2, 3, 4, 8].

The  $\delta_q$  in our amplitude that connects to physical quark lines have units of time, giving us inverse energy relation. Raising  $1/E$  to the first power provided too strong an energy dependence for positions of the dips. With  $\delta_q$  proportional to  $(1/m)(m/E)^p$ ,

(H.M.Fried, Y.Gabellini, T.Grandou, Y-Ming Sheu, PHT. Annals of Physics 2015)

Figure 12-1: Elastic differential cross-section is most simply calculated from exchange of Gluon Bundles between hadrons and exchange of Gluon Bundles between hadrons with an additional one-quark-loop. The restriction to one loop is a first approximation.

the power  $p$  can be deduced from data. See figure 12-3. The parameters coupling  $g$ , (re)normalization constants  $\kappa$  and  $p$ , and  $m$ , mass scale,  $\beta$ 's will be determined from experiment. Note that the  $\beta$ 's can be computed exactly with random matrix methods, but for now, we shall let experiments give us this value.

## 12.2 Elastic Scattering Amplitude with Gluon Bundle and One quark loop term

Amplitude for gluon bundles and one loop between two hadrons is given by Eq. 11.21, where each hadron is comprised of 3 average quarks. See figure 12-3, 12-4, 12-5, 12-6, 12-

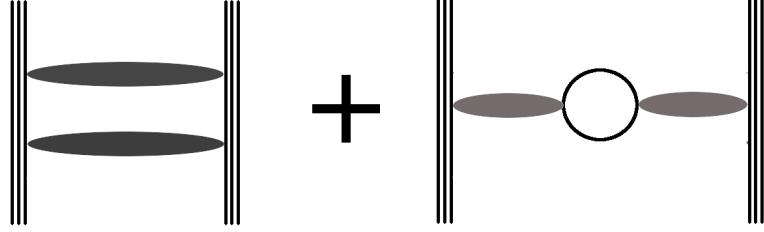

Figure 12-2: Gluon Bundles term (two bundles because one bundle is anti-symmetric) plus Gluon-Bundle-One-Closed-Quark-Loop term

7 and 12-8. The parameters resulted from this amplitude are

$$g = 2.9$$

$$m = 2m_\pi$$

$$p = 0.01 \quad (12.1)$$

$$\beta_{ext} = 3.0$$

$$\kappa = 0.0296$$

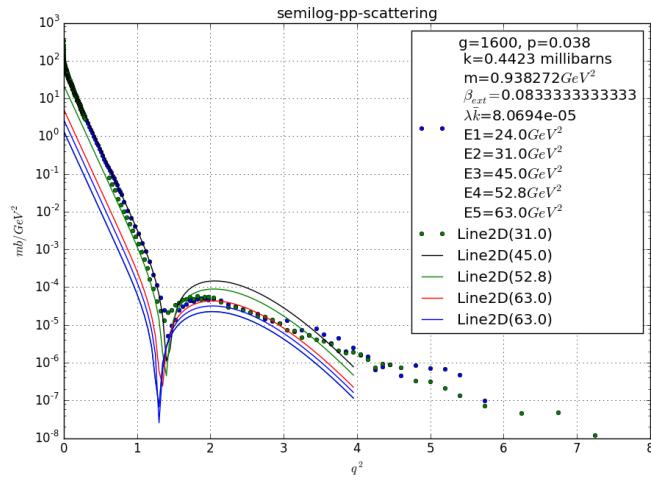

Figure 12-3: Early comparisons of Gluon Bundle exchanges and the one-loop-term amplitude compares well with Intersecting Storage Ring data of elastic pp-scattering. Data points are in small circular points. Our calculations are solid lines. There is the expected movement of the dip to smaller  $q^2$  as energy,  $\sqrt{s}$  is increased, [2, 3, 4, 8].

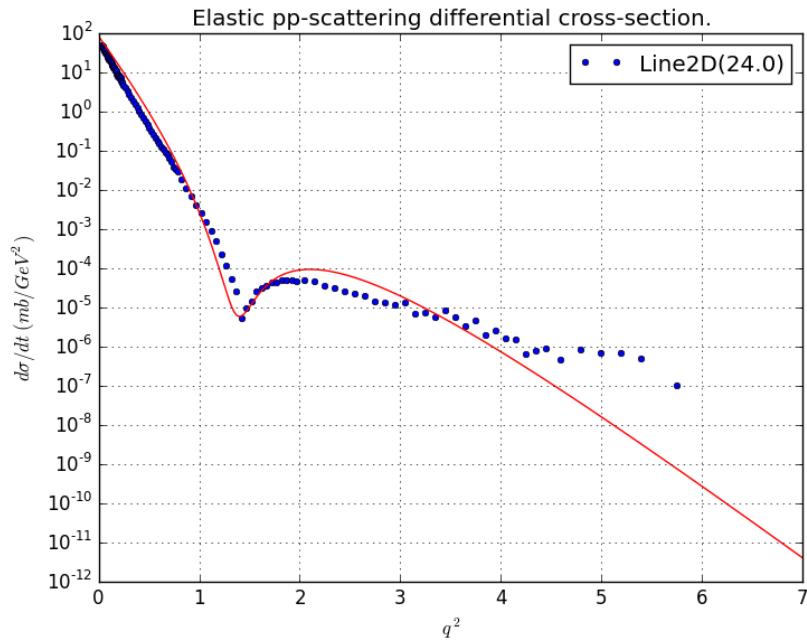

Figure 12-4: 24 GeV ISR fit using amplitude with gluon bundles and one loop term.

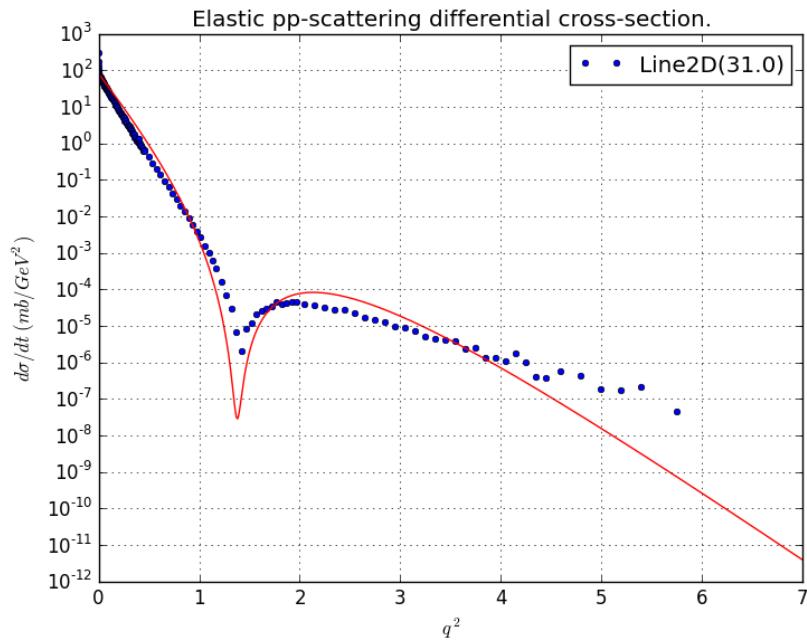

Figure 12-5: 31 GeV ISR fit using amplitude with gluon bundle and one loop term.

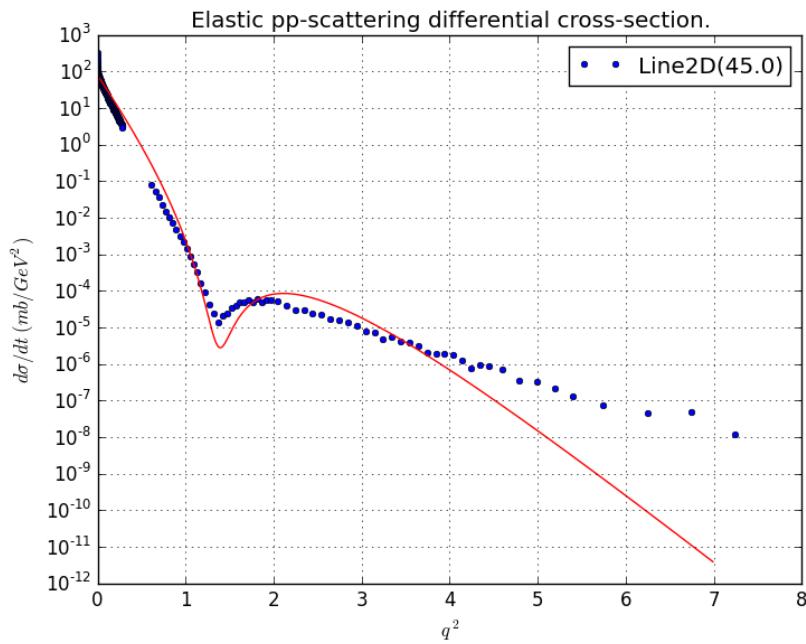

Figure 12-6: 45 GeV ISR fit using amplitude with gluon bundle and one loop term.

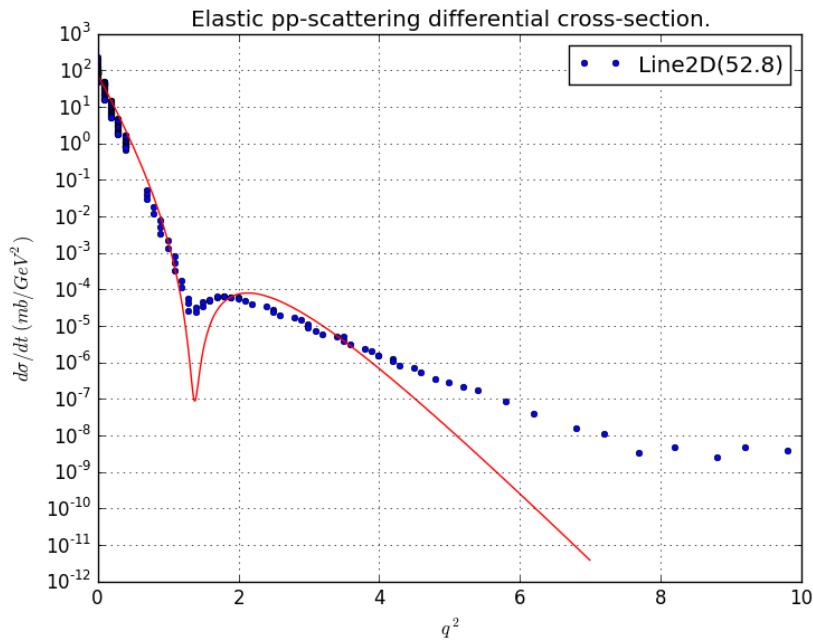

Figure 12-7: 53 GeV ISR fit using amplitude with gluon bundle and one loop term.

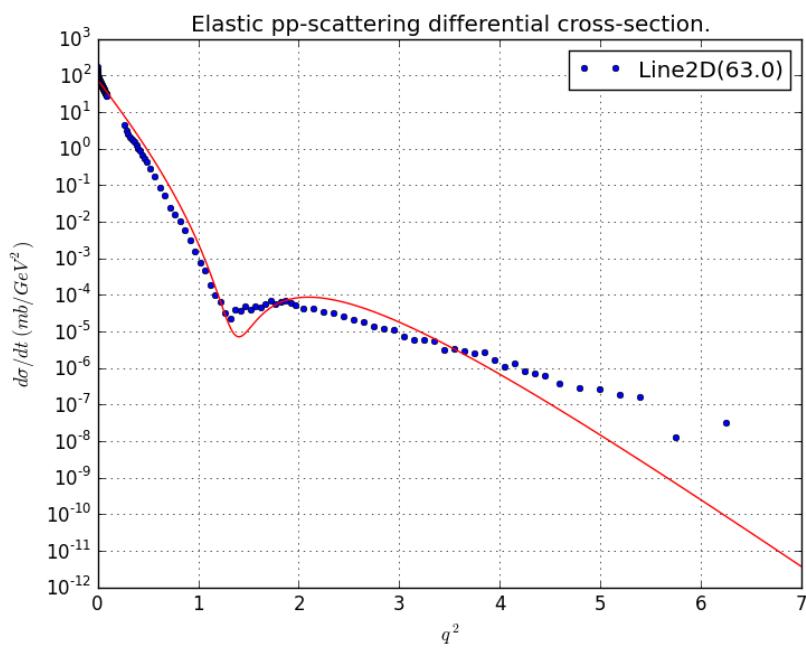

Figure 12-8: 63 GeV ISR fit using amplitude with gluon bundle and one loop term.

## 12.3 Elastic Scattering Amplitude with Gluon Bundle and Infinite summed loop chains

For the full elastic scattering amplitude given by Eq. 11.22, there are 9 possible ways for the left hand side quarks in a proton to connect to the right hand side quarks of the other proton, corresponding to  $3 \times 3$  different ways the chain can be exchanged. Consider the left hand side quark touching the external quark, there are 3 colors and 2 transverse choices that can be made for the left hand side of that GB.

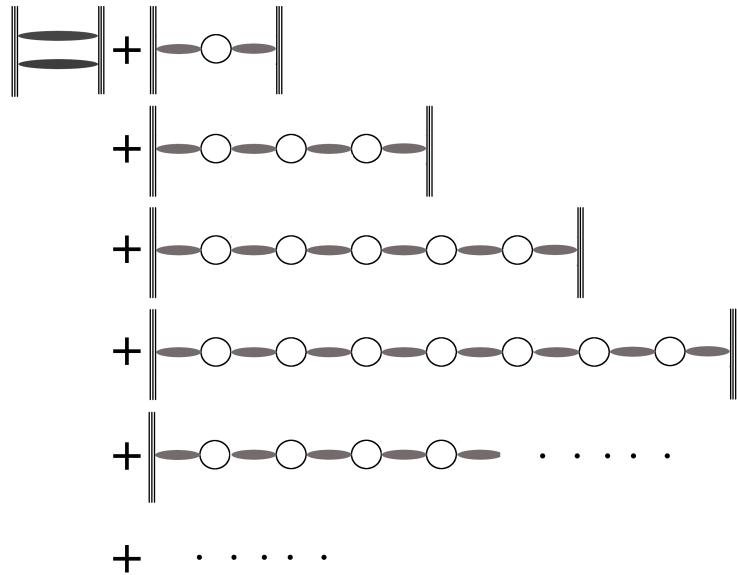

Figure 12-9: Complete elastic scattering amplitude,  $T$ . Gluon Bundles term (two bundles because one bundle is anti-symmetric) plus  $\sum$  of infinite chains of loops.

If the right hand side of that GB is to have a different color than the left hand side, with the same transverse coordinate, there will then be an extra factor of 2 choices, as it touches the first left hand side loop. And so there would seem to be an extra factor of 2 for choices of the right hand side quark.

Parameters with the entire infinite loop chain and gluon bundle amplitude resulted

in

$$g = 6.0$$

$$m_{ext} = 2m_\pi, \quad m_{int} = 12m_\pi$$

$$\beta_{ext} = 3.0, \quad \beta_{int} = 1/9 \quad (12.2)$$

$$p = 0.1$$

$$\kappa = 0.000265$$

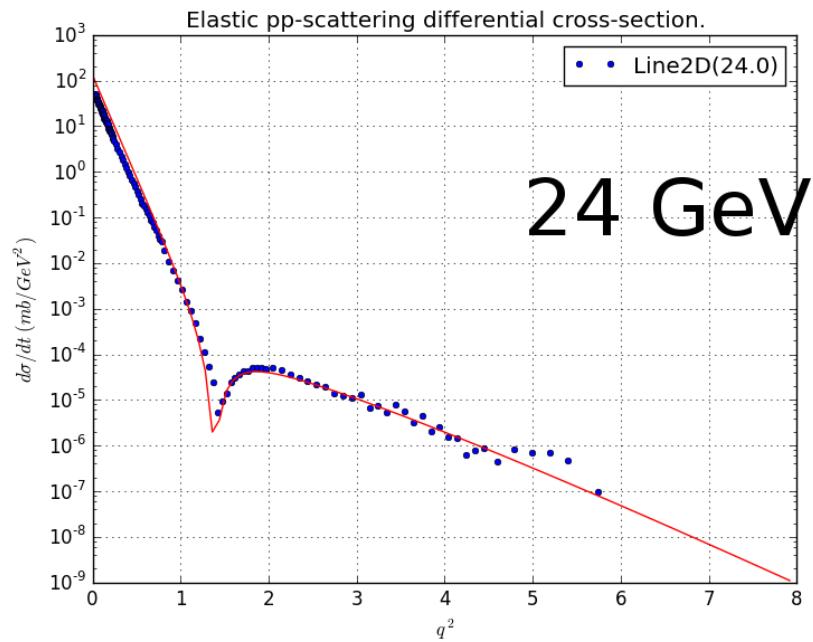

Figure 12-10: 24 GeV ISR fit with infinite loop chains summed.

For LHC's energy of 7 TeV, total cross section should become more relevant.

# Chapter 13

## Extension to LHC energies and beyond. Summary and Conclusions.

### 13.1 Total cross section

At 7  $TeV$  and above, we feel it is important to consider to total cross section,  $\sigma$ ,

$$\sigma = \frac{4\pi}{k} \Im[T(0)] \quad (13.1)$$

is proportional to the imaginary part of the foward amplitude,  $T(0)$ . As first derived by Cheng and Wu in their seminal paper [15], that the cross-section should rise with increasing center of mass energy,

$$\ln^2 \left( \frac{(s/s_0)^a}{\ln^2(s/s_0)} \right) \quad (13.2)$$

and later confirmed by experiments. Data from Totem collaboration at the LHC [18, 19], Figure 13-1 shows that at LHC energies, the total cross-section is much higher than at the ISR energies this report is focused on.

In our renormalization scheme where the  $\delta_q$  that connects to a physical quark is given the factor  $(\frac{m}{E})^{2p}$ . Intuitively we feel there should be energy dependence on this  $p$ . This work towards the LHC energies is currently underway.

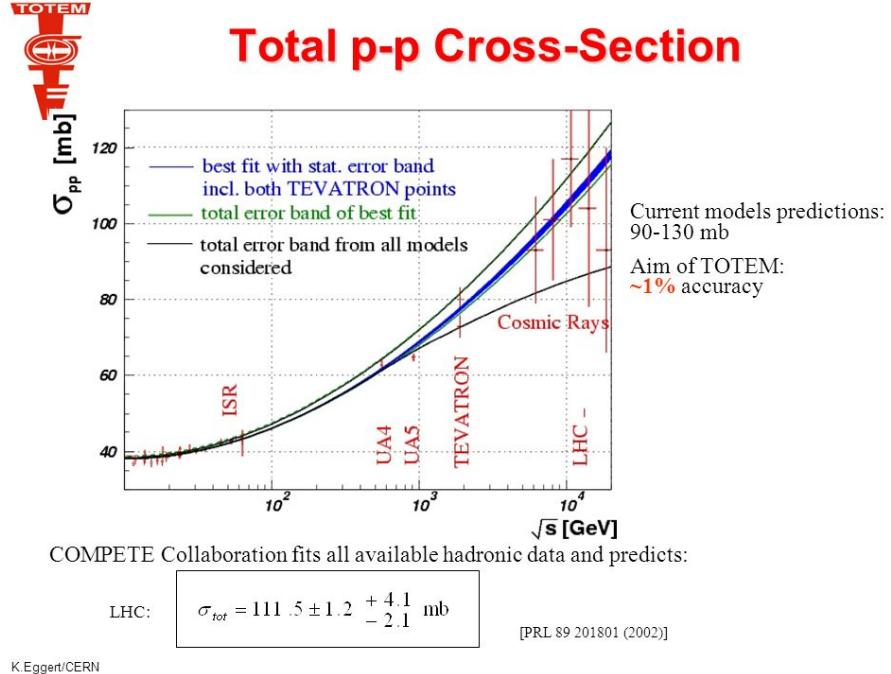

Figure 13-1: Totem’s total cross section shows a rise with increasing beam energy.

## 13.2 Summary and Conclusions

What we have done is began with the Schwinger Action, write down the QCD Lagrangian, imposing that quarks’s field must include an imprecision,  $\varphi(b)$ . From there, through Halpern’s Functional in addition to Fradkin’s representations, we get explicitly gaussian operations on gaussian integrals. This is possible only in the non-abelian case, which is quite surprising that QCD is perhaps an easier problem than QED. All of the above gives a finite, exact, gauge-invariant, non-perturbative answers to QCD processes and can be done exactly.

1. Gauge invariance is insured in it’s strongest form by means of being Gauge-independent.
2. Both Casimir,  $C_2$  and  $C_3$  invariants are preserved.
3. A new property in Effective Locality arose and simplifies all quark/quark processes correlations, without approximation, without exception.
4. Individual gluons have disappeared, giving instead, the entire sum of all gluons

exchanges, a Gluon Bundle.

5. Quark binding is obtained by the vital change of sign in its corresponding potential.
6. The mass of a pion is obtained and in the right order.
7. Nucleon binding, the simplest one in a deuteron is produced.

We, at this point, introduced our particular choice of renormalization where  $\delta^2\ell = \kappa$  is assumed finite, we have simplified all loop graphs to simply loop chains. Taking all the SU(3) color fields angles to be of the same order, where  $\sum_A \chi^2$  is averaged as  $R^2$ , we arrived at elastic scattering amplitudes that we can compare against experiment. Our differential cross-section, with only the coupling constant  $g$ , renormalization constants  $p$  and  $\kappa$ , and finally the bound state mass factor  $m_{ext}$  and  $m_{int}$  to be determined from experiments. The results compare remarkably well at ISR energies including energy dependencies that shifts the diffraction dip to lower  $q^2$ , and the form of the curve. Certainly, comparison with LHC data is the next logical step and is underway.

We feel, at this stage, this formalism of QCD is on good footing. Perhaps QCD can be raised to the level of QED as a true theory of nature.

# Appendix A

## Appendix A

### A.1 Modified Fradkin's Representation of Green's function and Closed-Fermion-Loop Functional

The causal Green's function in Eq. (??) can be written as [23]

$$\mathbf{G}_c[A] = [m + i\gamma \cdot \Pi][m + (\gamma \cdot \Pi)^2]^{-1} = [m + i\gamma \cdot \Pi] \cdot i \int_0^\infty ds e^{-ism^2} e^{is(\gamma \cdot \Pi)^2}, \quad (\text{A.1})$$

where  $\Pi = i[\partial_\mu - igA_\mu^a \tau^a]$  and  $(\gamma \cdot \Pi)^2 = \Pi^2 + ig\sigma_{\mu\nu} \mathbf{F}_{\mu\nu}^a \tau^a$  with  $\sigma_{\mu\nu} = \frac{1}{4}[\gamma_\mu, \gamma_\nu]$ . Following the Fradkin's method and replacing  $\Pi_\mu$  with  $i\frac{\delta}{\delta v_\mu}$ , one obtains

$$\begin{aligned} & \mathbf{G}_c(x, y|A) \\ &= i \int_0^\infty ds e^{-ism^2} \cdot e^{i \int_0^s ds' \frac{\delta^2}{\delta v_\mu^2(s')}} \cdot \left[ m - \gamma_\mu \frac{\delta}{\delta v_\mu(s)} \right] \delta(x - y + \int_0^s ds' v(s')) \\ & \quad \times \left( \exp \left\{ -ig \int_0^s ds' \left[ v_\mu(s') A_\mu^a (y - \int_0^{s'} v) \tau^a + i\sigma_{\mu\nu} \mathbf{F}_{\mu\nu}^a (y - \int_0^{s'} v) \tau^a \right] \right\} \right)_{+|_{v_\mu \rightarrow 0}}. \end{aligned} \quad (\text{A.2})$$

Then, one can insert [26]

$$1 = \int d[u] \delta(u(s') - \int_0^{s'} ds'' v(s'')) \quad (\text{A.3})$$

and replace the delta-functional  $\delta(u(s') - \int_0^{s'} ds'' v(s''))$  with a functional integral over

$\Omega$ , then the Green's function becomes [59]

$$\begin{aligned}
& \mathbf{G}_c(x, y|A) \\
= & i \int_0^\infty ds e^{-ism^2} e^{-\frac{1}{2}\text{Tr ln}(2h)} \int d[u] e^{\frac{i}{4} \int_0^s ds' [u'(s')]^2} \delta^{(4)}(x - y + u(s)) \\
& \times \left[ m + ig\gamma_\mu A_\mu^a(y - u(s))\tau^a \right] \left( e^{-ig \int_0^s ds' u'_\mu(s') A_\mu^a(y - u(s')) \tau^a + g \int_0^s ds' \sigma_{\mu\nu} \mathbf{F}_{\mu\nu}^a(y - u(s')) \tau^a} \right)_+,
\end{aligned} \tag{A.4}$$

where  $h(s_1, s_2) = \int_0^s ds' \theta(s_1 - s')\theta(s_2 - s')$ . To remove the  $A_\mu^a$ -dependence out of the linear (mass) term, one can replace  $igA_\mu^a(y - u(s))\tau^a$  with  $-\frac{\delta}{\delta u'_\mu(s)}$  operating on the ordered exponential so that

$$\begin{aligned}
\mathbf{G}_c(x, y|A) &= i \int_0^\infty ds e^{-ism^2} e^{-\frac{1}{2}\text{Tr ln}(2h)} \int d[u] e^{\frac{i}{4} \int_0^s ds' [u'(s')]^2} \delta^{(4)}(x - y + u(s)) \\
&\times \left[ m - \gamma_\mu \frac{\delta}{\delta u'_\mu(s)} \right] \left( e^{-ig \int_0^s ds' u'_\mu(s') A_\mu^a(y - u(s')) \tau^a + g \int_0^s ds' \sigma_{\mu\nu} \mathbf{F}_{\mu\nu}^a(y - u(s')) \tau^a} \right)_+.
\end{aligned} \tag{A.5}$$

To extract the  $A$ -dependence out of the ordered exponential, one may use the identities

$$\begin{aligned}
1 &= \int d[\alpha] \delta[\alpha^a(s') + gu'_\mu(s') A_\mu^a(y - u(s'))] \\
1 &= \int d[\Xi] \delta[\Xi_{\mu\nu}^a(s') - g\mathbf{F}_{\mu\nu}^a(y - u(s'))]
\end{aligned} \tag{A.6}$$

so that

$$\begin{aligned}
& \left( e^{-ig \int_0^s ds' u'_\mu(s') A_\mu^a(y - u(s')) \tau^a + g \int_0^s ds' \sigma_{\mu\nu} \mathbf{F}_{\mu\nu}^a(y - u(s')) \tau^a} \right)_+ \\
= & \mathcal{N}_\Omega \mathcal{N}_\Phi \int d[\alpha] \int d[\Xi] \int d[\Omega] \int d[\Phi] \left( e^{i \int_0^s ds' [\alpha^a(s') - i\sigma_{\mu\nu} \Xi_{\mu\nu}^a(s')] \tau^a} \right)_+ \\
& \times e^{-i \int ds' \Omega^a(s') \alpha^a(s') - i \int ds' \Phi_{\mu\nu}^a(s') \Xi_{\mu\nu}^a(s')} \\
& \times e^{-ig \int ds' u'_\mu(s') \Omega^a(s') A_\mu^a(y - u(s')) + ig \int ds' \Phi_{\mu\nu}^a(s') \mathbf{F}_{\mu\nu}^a(y - u(s'))},
\end{aligned} \tag{A.7}$$

where  $\mathcal{N}_\Omega$  and  $\mathcal{N}_\Phi$  are constants which normalize the functional representations of the delta-functionals. All  $A$ -dependence is removed from the ordered exponentials and the resulting form of the Green's function is exact (it entails no approximation).

Alternatively, extracting the  $A$ -dependence out of the ordered exponential can also be achieved by using the functional translation operator. One writes

$$\left( e^{+g \int_0^s ds' [\sigma_{\mu\nu} \mathbf{F}_{\mu\nu}^a(y-u(s')) \tau^a]} \right)_+ = e^{g \int_0^s ds' \mathbf{F}_{\mu\nu}^a(y-u(s')) \frac{\delta}{\delta \Xi_{\mu\nu}^a(s')}} \cdot \left( e^{\int_0^s ds' [\sigma_{\mu\nu} \Xi_{\mu\nu}^a(s') \tau^a]} \right)_+ \Big|_{\Xi \rightarrow 0}. \quad (\text{A.8})$$

For the closed-fermion-loop functional  $\mathbf{L}[A]$ , one can write [23]

$$\mathbf{L}[A] = -\frac{1}{2} \int_0^\infty \frac{ds}{s} e^{-ism^2} \left\{ \text{Tr} \left[ e^{-is(\gamma \cdot \Pi)^2} \right] - \{g = 0\} \right\}, \quad (\text{A.9})$$

where the trace sums over all degrees of freedom. The Fradkin's representation proceeds along the same steps as in the case of  $\mathbf{G}_c[A]$ , and the closed-fermion-loop functional reads

$$\begin{aligned} \mathbf{L}[A] = & -\frac{1}{2} \int_0^\infty \frac{ds}{s} e^{-ism^2} e^{-\frac{1}{2} \text{Tr} \ln(2h)} \\ & \times \int d[v] \delta^{(4)}(v(s)) e^{\frac{i}{4} \int_0^s ds' [v'(s')]^2} \\ & \times \int d^4x \text{tr} \left( e^{-ig \int_0^s ds' v'_\mu(s') A_\mu^a(x-v(s')) \tau^a + g \int_0^s ds' \sigma_{\mu\nu} \mathbf{F}_{\mu\nu}^a(x-v(s')) \tau^a} \right)_+ \\ & - \{g = 0\}, \end{aligned} \quad (\text{A.10})$$

where the trace now sums over color and spinor indices. Also, Fradkin's variables have been denoted by  $v(s')$ , instead of  $u(s')$ , in order to distinguish them from those

appearing in the Green's function  $\mathbf{G}_c[A]$ . One finds

$$\begin{aligned}
\mathbf{L}[A] = & -\frac{1}{2} \int_0^\infty \frac{ds}{s} e^{-ism^2} e^{-\frac{1}{2}\text{Tr} \ln(2h)} \quad (A.11) \\
& \times \mathcal{N}_\Omega \mathcal{N}_\Phi \int d^4x \int d[\alpha] \int d[\Omega] \int d[\Xi] \int d[\Phi] \\
& \times \int d[v] \delta^{(4)}(v(s)) e^{\frac{i}{4} \int_0^s ds' [v'(s')]^2} \\
& \times e^{-i \int ds' \Omega^a(s') \alpha^a(s') - i \int ds' \Phi_{\mu\nu}^a(s') \Xi_{\mu\nu}^a(s')} \cdot \text{tr} \left( e^{i \int_0^s ds' [\alpha^a(s') - i \sigma_{\mu\nu} \Xi_{\mu\nu}^a(s')] \tau^a} \right)_+ \\
& \times e^{-ig \int_0^s ds' v'_\mu(s') \Omega^a(s') A_\mu^a(x-v(s')) - 2ig \int d^4z (\partial_\nu \Phi_{\nu\mu}^a(z)) A_\mu^a(z)} \\
& \times e^{+ig^2 \int ds' f^{abc} \Phi_{\mu\nu}^a(s') A_\mu^b(x-v(s')) A_\nu^c(x-v(s'))} \\
& - \{g = 0\},
\end{aligned}$$

where the same properties as those of  $\mathbf{G}_c[A]$  can be read off explicitly and the  $A$ -dependence is at most Gaussian.
