Abstract

The decay amplitudes for $B^0 \to D^+_s D_s$ and $B^0_s \to D^+ D$ have no factorizable contributions. We suggest that dominant contributions to the decay amplitudes arise from two chiral loop contributions and one soft gluon emission contribution. Then we determine branching ratios $BR(B^0 \to D^+_s D_s) \approx 7 \times 10^{-5}$ and $BR(B^0_s \to D^+ D) \approx 1 \times 10^{-3}$.

Numerous experimental data coming from BaBar, Belle and Tevatron on $B$ meson decays stimulate many studies of their decay mechanism. Through decades the factorization assumption has been used in calculations of the decay amplitudes. Recently, it has been shown [1] that some classes of $B$-meson decay amplitudes exhibit QCD factorization. This means that, up to $s = \langle m_{B^0} \rangle$ (calculable) and $Q_{CD} \approx m_b$ (not calculable), their amplitudes factorize into the product of two matrix elements of weak currents. Typically, the decay amplitudes which factorize in this sense are $B \to D$ and $B \to K$ where the energy release is big compared to the light meson masses. However, for decays where the energy release is of order 1 GeV, QCD factorization is not expected to hold. Here we discuss the dominant contributions in $B^0 \to D^+_s D_s$ and $B^0_s \to D^+ D$ [2]. At quark level these decays occur through the annihilation mechanism $b \to c \bar{c}$ and $b \to b \bar{c}$, respectively (Fig. 1). However, within the factorized limit the annihilation mechanism will give a zero amplitude due to current conservation, as for the $D^0 \to K^0 \bar{K}^0$ decay [3]. The axial part of the weak current might lead to non-zero factorized contributions if one of $D$-mesons in the final state is a vector meson $D^*$. Such contributions are proportional to the numerically small Wilson coefficient $C_1$, which we will neglect in our analysis. In contrast, the typical factorized decay modes which proceed through the spectator mechanism, say $B^0 \to D^+ D_s$, are proportional to the numerically larger Wilson coefficient $C_2$. If one or both of charm mesons

Contributed Paper for LPO 3

1
in this decay are vector mesons, such amplitudes will give non-factorizable chiral loop contributions to the process $B^0 \rightarrow D^+_s D_s$ due to $K^0$-exchange. We determine these chiral loop contributions.

There are also non-factorizable contributions due to soft gluon emission. Such contributions can be calculated in terms of the (lowest dimension) gluon condensate within a recently developed Heavy Light Chiral Quark Model (HL QM) [9], which is based on Heavy Quark Effective Theory (HQET) [5]. This model has been applied to processes with $B$-mesons in [6,7]. The gluon condensate contributions are also proportional to the Wilson coefficients $C_i$. We follow the standard approach [3] for non-leptonic decays where one constructs an effective Lagrangian $L_W$ in terms of quark operators multiplied by Wilson coefficients. All information of the short distance (SD) loop effects above a renormalization scale of order $m_b$, within Heavy Quark Effective Theory (HQET) [5], the effective Lagrangian $L_W$ can be evolved down to the scale $\Lambda' = \Lambda$ [9,10].

The use of factorization is illustrated in the $B^0 \rightarrow D^+_s D_s$ decay:

$$h_{D_s} D^+_s j_W \bar{B}^0 j_F = (C_2 + \frac{1}{N_c} C_1) h_{D_s} D^+_s \bar{B}^0,$$  \hspace{1cm} (1)

The coefficients $C_{1,2}$ are Wilson coefficients for the operators containing the product of two left-handed currents. In our notation $C_1 = \frac{6}{G_F} V_{cb} V_{cs} a_1$, where the $a_i$ are dimensionless, $G_F$ is the Fermi coupling, $V_{ij}$ are CKM parameters. Numerically, $a_1 = 10^{-1}$ and $a_2 = 1$ at the scale $\Lambda = m_b$, and $a_1 j^0 (3)$ and $a_2 j^0 (1)$ at $1 \text{ GeV}$ [9,10]. Penguin operators may also contribute, but have rather small Wilson coefficients.

The factorized amplitude for $B^0 \rightarrow D^+_s D_s$ is presented in Fig. 1, and is given by

$$h_{D_s} D^+_s j_W \bar{B}^0 j_F = 4(C_1 + \frac{1}{N_c} C_2) h_{D_s} D^+_s \bar{B}^0 i_d 5 c \bar{d} h_{D_s} D^+_s \bar{B}^0 i_F;$$  \hspace{1cm} (2)

Unless one or both of the $D$-mesons in the final state are vector mesons, this matrix element is zero due to current conservation:

$$h_{D_s} D^+_s \bar{B}^0 i_d 5 c \bar{d} h_{D_s} D^+_s \bar{B}^0 i_F = 0;$$  \hspace{1cm} (3)

Our approach is based on the use of bosonized currents [2] and by using them we write down the amplitudes for $B^0 \rightarrow D^+_s D_s$. To calculate the chiral loop amplitudes we need the factorized amplitudes for $B^0 \rightarrow D^+_s D_s$ and $B^0 \rightarrow D^+_s D_s$, which proceed through the spectator mechanism as in Fig. 3. In this case the leading chiral coupling results from the coupling between a pseudoscalar meson $H$, vector meson $V$, and a light pseudoscalar $M (= \eta K)$, denoted by $g$. After use of bosonized currents [2], we obtain the following chiral loop amplitude for the process $B^0 \rightarrow D^+_s D_s$ from Fig. 3:

$$A(B^0 \rightarrow D^+_s D_s) = (V_{cd} = V_{cs}) A(B^0 \rightarrow D^+_d D_s) R;$$  \hspace{1cm} (4)

where $A(B^0 \rightarrow D^+_d D_s)$ stands for the factorized amplitude for the process $B^0 \rightarrow D^+_d D_s$ and the quantity $R$ is a sum of contributions from the left and right parts of Fig. 3.
Figure 1: Factorized contribution for $\overline{B}^0 \rightarrow D_s^+ D_s$ through the annihilation mechanism, which give zero contributions if both $D_s^+$ and $D_s$ are pseudoscalars. The double dashed lines represent heavy mesons, the double lines represent heavy quarks, and the single lines light quarks.

Figure 2: Factorized contribution for $\overline{B}^0 \rightarrow D_s^+ D_s$ through the spectator mechanism, which does not exist for decay mode $\overline{B}^0 \rightarrow D_s^+ D_s$ we consider in this paper.

3 respectively [2]. In the $\overline{MS}$ scheme we obtained

$$R = \frac{m_R^2}{(4\pi f)^2} g_A^2 \frac{(! + 1)}{(! + 1)} \ln \frac{m_R^2}{\Lambda^2} \frac{1}{1} ;$$

which means that the amplitude gets an imaginary part. Numerically, we end [2]:

$$R = 0.12 \pm 0.26i.$$  

The genuine nonfactorizable part for $\overline{B}^0 \rightarrow D_s^+ D_s$ can, by means of Fierz transformations and identities for the product of two color matrices, be written in terms of colored currents

$$\not{h} D_s \not{J}_W \not{B}^0 i_{NF} = 8 C_2 \not{h} D_s \not{J}(c_L \not{t}^c b_L) (c_L \not{t}^c b_L) \not{B}^0 i ;$$
With our approach, this amplitude is written in a quasi-factorized way in terms of matrix elements of colored currents:

\[ h D_s^+ D_s^- \mathcal{J}_W \overline{B^0} \mathcal{G}^F_{W} = 8 C_2 h D_s^+ D_s^- \mathcal{O}_L t^6 \mathcal{G}_L t^b \mathcal{G} \overline{B^0} i; \]

where a \( G \) in the bra-kets symbolizes emission of one gluon (from each current) as visualized in Fig. 4. In order to calculate the matrix elements in [3], we have used [2] the Heavy Light Chiral Quark Model (HLQM) recently developed in [4], which incorporates emission of soft gluons modeled by a gluon condensate. Then we defined a quantity \( R_G \) for the gluon condensate amplitude analogously to \( R \) in [4] and [5] for chiral loops. Numerically, we determined [2] that the ratio between the two amplitudes is

\[ R_G' = 0.055 + 0.16i; \]

which is of order one third of the chiral loop contribution in eq. [3].

Adding the amplitudes \( R \) and \( R_G \) and multiplying with the Wilson coefficient [2,10] \( a_2' = 1.33 + 0.2i \), we obtain the quantity:

\[ R_T a_2 (R + R_G) = 0.26 + 0.11i; \]

We have found that the amplitude for \( \overline{B^0} \to D_s^+ D_s^- \) is of order 15\% 20\% of the factorizable amplitude for \( \overline{B^0} \to D_s^+ D_s^- \), before the different CKM factors are taken into account.
Finally, we predict [2] that the branching ratios are

\[ \text{BR} \left( \bar{B}_d^0 \rightarrow D_s^+ D_s \right) \sim 7 \times 10^{-5} ; \quad \text{BR} \left( \bar{B}_s^0 \rightarrow D^+ D \right) \sim 1 \times 10^{-3} ; \quad (12) \]

The current searches at BaBar and Belle might soon result in the limit on the rate \( \bar{B}_0^0 \rightarrow D^+_s D_s \). However, the \( \bar{B}_s^0 \rightarrow D^+ D \) mode will be accessible at Tevatron and later at LHC.
